We present the full analytic result for the three loop angle-dependent cusp anomalous dimension in QCD. With this result, infrared divergences of planar scattering processes with massive particles can be predicted to that order. Moreover, we define a closely related quantity in terms of an effective coupling defined by the lightlike cusp anomalous dimension. We find evidence that this quantity is universal for any gauge theory and use this observation to predict the nonplanar $n_f$-dependent terms of the four loop cusp anomalous dimension.

Understanding the structure of soft and collinear divergences is of great theoretical interest in quantum field theory. It is also relevant for phenomenological applications such as the production of heavy particles at the LHC, where effects from soft gluon radiation need to be resummed in order to improve theoretical predictions.

It is well known that the infrared (or long-distance) asymptotics of scattering amplitudes is described by correlation functions of Wilson lines pointing along the momenta of the scattered particles [1,2]. The latter satisfy evolution equations with the corresponding anomalous dimension being, in general, a matrix in color space. In the planar limit, this matrix is expressed in terms of the two-line cusp anomalous dimension [3]. The two loop result for this fundamental quantity has been known for more than 25 years [4]; see, also, Ref. [5]. Here we report on the full result for the cusp anomalous dimension in QCD at three loops.

To compute the cusp anomalous dimension, we consider the vacuum expectation value of the Wilson line operator

$$W = \frac{1}{N} \langle 0 | \text{tr} \left[ P \exp \left( i \int_C dx A(x) \right) \right] | 0 \rangle,$$

with $A_\mu(x) = A_\mu^a(x) T^a$ and $T^a$ being the generators of the fundamental representation of the $SU(N)$ gauge group. Here, the integration contour $C$ is formed by two segments along directions $v_1^\mu$ and $v_2^\mu$ (with $v_1^2 = v_2^2 = 1$), with (Euclidean space) cusp angle $\phi$,

$$\cos \phi = v_1 \cdot v_2.$$

FIG. 1. Sample Feynman diagram producing a contribution to the three loop cusp anomalous dimension in QCD. Thick lines denote two semi-infinite segments forming a cusp of angle $\phi$, and wavy lines represent gauge fields.
non-negative values. Because of the symmetry $x \rightarrow 1/x$ of the definition (3), we can assume $0 < x < 1$ without loss of generality.

We chose to perform the calculation in momentum space. We generated all Feynman diagrams contributing to $W$ up to three loops, in an arbitrary covariant gauge. This was done with the help of the computer programs QGRAF and FORM [6]. Using integration by parts relations [7], we found that a total of 71 master integrals was required. We derived differential equations for them in the complex variable $x$ defined in Eq. (3). Switching to a basis of master integrals $\tilde{f}(x, \epsilon)$ as suggested in Ref. [8], we found the expected canonical form of the differential equations [9],

$$\partial_x \tilde{f}(x, \epsilon) = \epsilon \left[ \frac{a}{x^2} + \frac{b}{x+1} + \frac{c}{x-1} \right] \tilde{f}(x, \epsilon),$$

with constant ($x$- and $\epsilon$-independent) matrices $a, b, c$.

Equation (4) has four regular singular points in $x$, namely, 0, 1, $-1$, and $\infty$. Thanks to the $x \rightarrow 1/x$ symmetry of the definition (3), only the first three are independent. They correspond, in turn, to the lightlike limit (infinite Minkowski angle), to the zero angle limit, and to the antiparallel lines limit. Requiring that the integrals be nonsingular in the straight-line case $x = 1$ allowed us to fix all except one of the boundary conditions, and we obtained the remaining one from Ref. [10].

It follows from Eq. (4) that the solution for $\tilde{f}$ in the $\epsilon$ expansion can be written in terms of iterated integrals with integration kernels $dx/x, dx/(x-1), dx/(x+1)$. The latter integrals are known as harmonic polylogarithms $H_{n_1,\ldots,n_l}(x)$ [11]. The indices $n_i$ can take values 0, 1, $-1$ corresponding to the three integration kernels, respectively.

To express our results up to three loops, we introduce the following functions [12]:

$$A_1(x) = \xi \frac{1}{2} H_1(y), \quad A_2(x) = \left[ \frac{\pi^2}{3} + \frac{1}{2} H_{1,1}(y) \right] + \xi \left[ -H_{0,1}(y) - \frac{1}{2} H_{1,1}(y) \right],$$

$$A_3(x) = \xi \left[ -\frac{\pi^2}{6} H_1(y) - \frac{1}{4} H_{1,1,1}(y) \right] + \xi^2 \left[ \frac{1}{2} H_{1,0,1}(y) + \frac{1}{4} H_{1,1,1}(y) \right],$$

$$A_4(x) = -\xi \left[ \frac{\pi^2}{6} H_{1,1}(y) - \frac{1}{4} H_{1,1,1}(y) \right] + \xi \left[ \frac{\pi^2}{3} H_{0,1,1}(y) + \frac{\pi^2}{6} H_{1,1,1}(y) + \frac{7}{4} H_{1,1,1,1}(y) + 3\zeta_3 H_1(y) \right] + \xi^2 \left[ -2H_{1,0,0,1}(y) - 2H_{0,1,0,1}(y) - 2H_{1,1,0,1}(y) - H_{1,0,1,1}(y) - H_{0,1,1,1}(y) \right] - \frac{3}{2} H_{1,1,1,1}(y),$$

$$A_5(x) = \xi \left[ \frac{\pi^4}{12} H_1(y) + \frac{\pi^2}{4} H_{1,1,1}(y) + \frac{5}{8} H_{1,1,1,1}(y) \right] + \xi^2 \left[ -\frac{\pi^2}{6} H_{1,0,1}(y) - \frac{\pi^2}{3} H_{0,1,1}(y) - \frac{\pi^2}{4} H_{1,1,1}(y) \right] - H_{1,1,1,0,1}(y) - \frac{3}{4} H_{1,0,1,1,1}(y) - H_{0,1,1,1,1}(y) - \frac{11}{8} H_{1,1,1,1,1}(y) - \frac{3}{2} H_{1,1,1,1}(y),$$

$$B_3(x) = \left[ -H_{1,0,1}(y) + \frac{1}{2} H_{0,1,1}(y) - \frac{1}{4} H_{1,1,1}(y) \right] + \xi \left[ 2H_{0,0,1}(y) + H_{1,0,1}(y) + H_{0,1,1}(y) + \frac{1}{4} H_{1,1,1}(y) \right],$$

$$B_5(x) = \frac{x}{1-x^2} \left[ -\frac{\pi^4}{60} H_{-1}(x) - \frac{\pi^4}{4} H_1(x) - 4H_{-1,0,-1,0,0}(x) + 4H_{-1,0,1,0,0}(x) - 4H_{1,0,-1,0,0}(x) + 4H_{1,0,1,0,0}(x) + 4H_{1,0,0,0,0}(x) + 4H_{1,0,0,0,0}(x) + 2\zeta_3 H_{-1,0}(x) + 2\zeta_3 H_{1,0}(x) \right],$$

where $\xi = (1 + x^2)/(1 - x^2)$ and $y = 1 - x^2$. The subscript of $A$ indicates the (transcendental) weight of the functions. Moreover, we introduce the abbreviation $A_i = A_i(x) - A_i(1)$ and similarly for $B_j$.

Performing the three loop computation, we reproduced the expected structure of UV divergences of $W$ in the $\overline{\text{MS}}$ scheme, as well as the heavy quark effective theory wave function renormalization [10], for arbitrary values of the gauge parameter in the covariant gauge. As yet another check, the dependence on the gauge parameter disappeared for the cusp anomalous dimension.
Let us write the expansion in the coupling constant as
\[ \Gamma_{\text{cusp}}(\alpha_s, x) = \sum_{k \geq 1} \left( \frac{\alpha_s}{\pi} \right)^k \Gamma_{\text{cusp}}^{(k)}(x). \] (6)

The previously known one and two loop [4] results can be written as
\[ \Gamma_{\text{cusp}}^{(1)} = C_F \tilde{A}_1, \] (7)
\[ \Gamma_{\text{cusp}}^{(2)} = \frac{1}{2} C_F C_A (\tilde{A}_3 + \tilde{A}_2) + \left( \frac{67}{36} C_F C_A - \frac{5}{9} C_F T_F n_f \right) \tilde{A}_1. \] (8)

At three loops, we find
\[ \Gamma_{\text{cusp}}^{(3)} = c_1 C_F C_A^2 + c_2 C_F (T_F n_f)^2 + c_3 C_F^2 T_F n_f \]
\[ + c_4 C_F C_A T_F n_f, \] (9)
with
\[ c_1 = \frac{1}{4} [\tilde{A}_5 + \tilde{A}_4 + \tilde{B}_3 + \tilde{B}_3] + \frac{67}{36} \tilde{A}_3 + \frac{29}{18} \tilde{A}_2 \]
\[ + \left( \frac{245}{96} + \frac{11}{24} \zeta_3 \right) \tilde{A}_1, \] (10)
\[ c_2 = -\frac{1}{27} \tilde{A}_1, \]
\[ c_3 = \left( \zeta_3 - \frac{55}{48} \right) \tilde{A}_1, \] (11)
\[ c_4 = -\frac{5}{9} [\tilde{A}_3 + \tilde{A}_2] - \frac{1}{6} \left( 7 \zeta_3 + \frac{209}{36} \right) \tilde{A}_1. \] (12)

Here, \( C_F = (N^2 - 1)/(2N) \) and \( C_A = N \) are the quadratic Casimir operators of the \( SU(N) \) gauge group in the fundamental and adjoint representation, respectively, \( n_f \) is the number of quark flavors, and \( T_F = 1/2 \).

The following comments are in order. The cusp anomalous dimension has a branch cut for \( x \) lying on the negative real axis. The results given in Eq. (9) are valid for \( 0 < x < 1 \) and can be analytically continued to other regions according to this choice of branch cuts [13].

The leading \( n_f^2 \) term in Eq. (9) is in agreement with the known result [14]. We reported on the \( n_f \)-dependent part of Eq. (9) in Ref. [15]. The expression for the coefficient \( c_1 \) is new.

As a check of our result, we can consider Minkowskian angles and take the lightlike limit, \( x = e^{-\theta} \) with \( \theta \to \infty \), of Eq. (9), where one expects the behavior [16]
\[ \Gamma_{\text{cusp}}(\alpha_s, x)^{x=0} = K(\alpha_s) \log(1/x) + \mathcal{O}(x^0), \] (13)
with \( K(\alpha_s) \) being the lightlike cusp anomalous dimension. To three loops, it is given by [17]
\[ K^{(1)} = C_F, \]
\[ K^{(2)} = C_A C_F \left( \frac{67}{36} - \frac{\pi^2}{12} \right) - \frac{5}{9} n_f T_F C_F, \]
\[ K^{(3)} = C_A^2 C_F \left( \frac{245}{96} - \frac{67 \pi^2}{216} + \frac{11 r_4}{720} + \frac{11}{24} \zeta_3 \right) \]
\[ + C_A C_F n_f T_F \left( \frac{209}{216} + \frac{5 \pi^2}{54} - \frac{7}{6} \zeta_3 \right) \]
\[ + C_F^2 n_f T_F \left( \zeta_3 - \frac{55}{48} \right) - \frac{1}{27} C_F (n_f T_F)^2. \] (14)

where \( K(\alpha_s) = \sum_{m \geq 1} (\alpha_s/\pi)^m K^{(m)} \). We found perfect agreement for all terms.

Finally, if the conformal symmetry of (massless) QCD were not broken, one would expect that the cusp anomalous dimension should be related in the antiparallel lines limit \( \phi = \pi - \delta, \delta \to 0 \), to the quark-antiquark potential [18] (at one loop order lower compared to \( \Gamma_{\text{cusp}} \)). Starting from Eq. (9), we indeed find perfect agreement with the result quoted in the second of Ref. [19], up to conformal symmetry breaking terms proportional to the QCD \( \beta \) function.

Our result for the cusp anomalous dimension is valid in the \( \overline{\text{MS}} \) (dimensional regularization) scheme. Going to the \( \overline{\text{DR}} \) (dimensional reduction) scheme amounts to a finite renormalization of the coupling constant. We can introduce a quantity \( \Omega \) which is the same in both schemes by switching from \( \alpha_s \) to an “effective coupling” \( a \),
\[ \Omega(a, x) = \Gamma_{\text{cusp}}(a_s, x), \quad a = \pi/C_F K(\alpha_s), \] (15)
where \( \Gamma_{\text{cusp}} \) and \( K(\alpha_s) \) are evaluated in the same scheme (and for the same theory). By construction, \( \Omega \) has the universal limit
\[ \Omega(a, x)^{x=0} = \frac{a}{\pi} C_F \log(1/x) + \mathcal{O}(x^0), \] (16)
as one can easily verify by comparing to Eq. (13).

Using the results up to three loops given in Eqs. (7)–(9) and (14), and expanding both sides of the first relation in Eq. (15) to third order in \( a_s \), we find
\[ \Omega(a, x) = \frac{a}{\pi} C_F \tilde{A}_1 + \left( \frac{a}{\pi} \right)^2 \frac{C_A C_F}{2} \left[ \tilde{A}_3 + \tilde{A}_2 - \frac{\pi^2}{6} \tilde{A}_1 \right] \]
\[ + \left( \frac{a}{\pi} \right)^3 \frac{C_F C_A^2}{4} \left[ \tilde{A}_5 + \tilde{A}_4 - \tilde{A}_2 + \tilde{B}_3 + \tilde{B}_3 \right] \]
\[ + \frac{\pi^2}{3} \tilde{A}_3 + \frac{\pi^2}{3} \tilde{A}_2 - \frac{\pi^4}{180} \tilde{A}_1 + \mathcal{O}(a^4). \] (17)

Remarkably, this quantity is independent of \( n_f \) to three loops. Comparing to Eq. (15), we see that this means that,
e.g., all $n_f$-dependent terms in $\Gamma_{\text{cusp}}^{(3)}$ are generated from lower loop terms when expanding $K(\alpha_s)$ in $\alpha_s$.

In Fig. 2, we plot the one, two, and three loop coefficients of $\Omega$ in an expansion of $a/\pi$, for Minkowskian angles $\theta$, i.e., $x = e^{-\theta}$ for the range $\theta \in [0, 4]$, and with the number of colors set to $N = 3$. Note that the $n_f$ dependence in QCD can be obtained from Eq. (15) and amounts to a rescaling of the coupling. At large $\theta$, the one loop contribution displays the linear behavior of Eq. (16), while the two and three loop contributions go to a constant, as expected. In the small-angle region, we have

$$\Omega(a, e^{-\theta}) = C_F \left[ \left( \frac{a}{\pi} \right)^{1/3} + \left( \frac{a}{\pi} \right)^2 \frac{C_A}{4} \left( 1 - \frac{\pi^2}{9} \right) \right.$$
$$+ \left( \frac{a}{\pi} \right)^3 \frac{C_A^2}{12} \left( -\frac{5}{3} \pi^2 + \frac{\pi^4}{6} - \frac{\pi^4}{20} \right) + O(a^4) \left. \right] \theta^2$$
$$+ O(\theta^4).$$

The observed $n_f$ independence of $\Omega(a, x)$ leads us to conjecture that the latter quantity is universal in gauge theories, i.e., independent of the specific particle content of the theory. Assuming this conjecture leads to a number of nontrivial predictions, as we discuss presently.

First, let us recall the known value for $K$ in $\mathcal{N} = 4$ super Yang-Mills theory (in the DR scheme) [20],

$$K_{\mathcal{N} = 4}(\alpha_s) = C_F \left[ \left( \frac{\alpha_s}{\pi} \right)^{- \frac{\pi^2}{12} C_A \left( \frac{\alpha_s}{\pi} \right)^2 \right.$$
$$+ \frac{1}{720} \pi^4 C_A^2 \left( \frac{\alpha_s}{\pi} \right)^3 + O(\alpha_s^4) \left. \right].$$

Plugging this formula and the result for $\Omega$ given in Eq. (17) into Eq. (15) then gives the previously unknown three loop result for the cusp anomalous dimension for the Wilson loop operator of Eq. (1) in that theory,

$$\Gamma_{\mathcal{N} = 4}(\alpha_s, x) = \frac{\alpha_s}{\pi} C_F \tilde{A}_1 + \frac{C_A C_F}{2} \left( \frac{\alpha_s}{\pi} \right)^2 \tilde{A}_2$$
$$+ \frac{C_F C_A^2}{4} \left( \frac{\alpha_s}{\pi} \right)^3 \left[ \tilde{A}_5 + \tilde{A}_4 - \tilde{A}_2 + \tilde{B}_5 + \tilde{B}_3 \right]$$
$$+ O(\alpha_s^4).$$

The two loop terms agree with Ref. [15]. As a test of the three loop prediction, we take the antiparallel lines limit and obtain

$$\Gamma_{\mathcal{N} = 4}(\alpha_s, x)^{\delta = 0} = -\frac{C_F \alpha_s}{\delta} \left( 1 - \left( \frac{\alpha_s}{\pi} \right) C_A \right.$$
$$+ \left( \frac{\alpha_s}{\pi} \right)^2 C_A^2 \left[ \frac{5}{4} + \frac{\pi^2}{4} - \frac{\pi^4}{64} \right] + O(\alpha_s^4) \left. \right)$$
$$+ O(\delta^0),$$

as expected from the direct calculation of the quark-antiquark potential [21].

Second, the conjecture of the $n_f$ independence of $\Omega$ can be used to predict the form of the nonplanar $n_f$ corrections that can first appear at four loops. The latter involve quartic Casimir operators of $SU(N_f)$, whose contribution we abbreviate by $C_4 = d_4^{abcd} d_4^{abcd}/N_A = (18 - 6N_f^2 + N_f^4)/(96N_f^2)$ [with $N_A$ the number of the $SU(N_f)$ generators] [22]. Consider a term in $\Gamma_{\text{cusp}}(\alpha_s, x)$ of the form $n_f(\alpha_s/\pi)^4 g(x) C_F C_A/4$, for some $g(x)$. Assuming that $\Omega$ defined in Eq. (15) is independent of $n_f$ then implies $g(x) = g_0 \tilde{A}_1$. Moreover, we can determine $g_0$ by comparing to the antiparallel lines limit. The expected relation to the known quark-antiquark potential computed (numerically) in Ref. [23] then yields $g_0 = -56.83(1)$.

In conclusion, we presented the full three loop result for the cusp anomalous dimension in QCD. The latter allows us to predict the infrared divergent part of planar scattering amplitudes of massive particles in QCD to that order. Moreover, our result can be applied to reduce theoretical uncertainties both in describing the scale dependence of heavy meson form factors [1,2] and in computing cross sections of top-antitop pair production in electron-positron annihilation and in hadronic collisions [5,24] (for a recent review, see Ref. [25]).

We observed that the result has a surprisingly simple dependence on the number of quark flavors $n_f$, which led us to define a quantity $\Omega$, independent of $n_f$ to three loops. If the latter is the same in any gauge theory, it could be studied using powerful integrability techniques that have been developed in $\mathcal{N} = 4$ super Yang-Mills theory; see Ref. [26] for more details.

[9] See Supplemental Material at http://link.aps.org/ supplemental/10.1103/PhysRevLett.114.062006 for the explicit basis choice \( f \), and the result for \( f \) in the \( e \) expansion, to the order required for this calculation.

[12] The function \( A_5 \) (and \( A_1 \) and \( A_3 \)) appeared previously in the result for the cusp anomalous dimension in \( N = 4 \) super Yang-Mills theory for a locally supersymmetric Wilson line operator [28].

[13] Note that \( \Gamma^{(0)}(\alpha_s, x) \) is expected to be related to \( \Gamma^{(0)}(\alpha_s, x) \) by crossing symmetry, i.e., the two functions should be equal, up to terms picked up by the analytic continuation. It turns out that all functions except \( B_5 \) contain rational factors that are symmetric under \( x \to -x \), and, therefore, the harmonic polylogarithms in these expressions can be written with argument \( 1 - x^2 \), and positive indices only. In contrast, the factor \( x/(1 - x^2) \) contained in \( B_5 \) is antisymmetric under \( x \to -x \), and so is the transcendental function multiplying it (up to terms coming from branch cuts).
