Differential inclusive-jet cross sections have been measured in photoproduction with the ZEUS detector at HERA at a centre-of-mass energy of $318$ GeV using an integrated luminosity of $300$ pb\(^{-1}\). Cross sections are presented as functions of the jet pseudorapidity, $\eta_{\text{jet}}$, and the jet transverse energy, $E_{\text{T, jet}}$. The cross sections have the potential to constrain the gluon density in the proton and the photon when included as input to fits to extract the proton parton distribution functions. Next-to-leading order QCD calculations give a good description of the measurements. The value of the strong coupling constant $\alpha_S(M_Z)$ has been extracted from the measurement. The energy-scale dependence of $\alpha_S$ has been determined in the range $17 < E_{\text{T, jet}}^2 < 71$ GeV.

1 Introduction

The study of jet production in $ep$ collisions at HERA has been well established as a testing ground of perturbative QCD. Jet cross sections provide precise determinations of the strong coupling constant, $\alpha_S$, and its scale dependence.

2 Cross sections in comparison to NLO-QCD predictions

Cross sections of inclusive-jet photoproduction were measured as functions of $E_{\text{T, jet}}$ and $\eta_{\text{jet}}$ in the kinematic range $Q^2 < 1$ GeV\(^2\), $142 < W_{\gamma p} < 293$ GeV, $E_{\text{T, jet}} > 17$ GeV and $-1 < \eta_{\text{jet}} < 2.5$. Jets were identified in the laboratory system using the $k_T$ cluster algorithm\(^4\) in the longitudinally invariant inclusive mode\(^5\) with the radius set to unity. Differential cross sections $d\sigma/dE_{\text{T, jet}}$ and $d\sigma/d\eta_{\text{jet}}$ are shown in figs. 1 and 2 respectively. The experimental errors include statistical and systematic errors except the jet-energy uncertainty which is shown separately. The cross sections are compared to NLO QCD predictions based on a program written by M. Klasen, T. Kleinwort and G. Kramer\(^1\). In this program, renormalisation and factorisation scale were set to $E_{\text{T, jet}}$. The implemented parton densities were ZEUS-S for the proton\(^2\) and GRV-HO for the photon\(^3\). The predictions were calculated on parton level, and corrected to hadron level using Monte Carlo simulations (PYTHIA and HERWIG). In general the data are well described by the predictions. However, some differences are visible at small $E_{\text{T, jet}}$ and large $\eta_{\text{jet}}$. The differences seen for $\eta_{\text{jet}}$ are reduced if the cut on $E_{\text{T, jet}}$ is raised to 21 GeV\(^6\).
Figure 1: The cross section $d\sigma/dE_T^{\text{jet}}$ compared to NLO QCD predictions. Shaded band: energy scale uncertainty of the jets. Hatched band: total theoretical uncertainty.

### 3 Dependence on model assumptions

To access the influence of the jet algorithm, cross sections were also studied with the jet algorithms anti-$k_T$ [7] and SIScone [8]. It has been noticed that no significant differences in the comparison between data and predictions were observed.

Another study was carried out using the Monte-Carlo program PYTHIA-MI for hadronisation corrections. This program includes non-perturbative multi-parton interactions [9]. As can be seen in Fig. 3, the prediction for the $\eta^{\text{jet}}$ distribution can be improved by including multi-parton interactions with an appropriate cut on the transverse momentum of the scattered parton. The prediction with $p_{T,\text{min}}^{\text{sec}} = 1.5$ GeV is closest to the data.

### 4 Dependence on the choice of PDFs

Predictions were calculated using the AFG04 [10] and CJK [11] photon PDFs instead of GRV-HO. Figure 4 shows the comparison between the measured cross sections and the predictions based on different photon PDFs. The uncertainty coming from the photon PDFs is largest at low $E_T^{\text{jet}}$ and high $\eta^{\text{jet}}$ and approximately of the order of the theoretical uncertainty. The measured cross sections are, on a similar level, sensitive to proton PDFs [6]. This implies that the measured cross sections have the potential to constrain the gluon density in photon and proton when used as input to a global fit.
5 Measurement of \( \alpha_S(M_Z) \) and the \( \alpha_S \) energy scale dependence

Differential cross sections \( d\sigma/d\eta^\text{jet} \) measured in the range \( 21 < E^\text{jet}_T < 71 \text{ GeV} \) were used to determine values of the strong coupling constant \( \alpha_S \) using the method presented previously [12]. The fit was restricted to \( E^\text{jet}_T < 71 \text{ GeV} \) because of the uncertainty coming from the photon PDFs for higher \( E^\text{jet}_T \) values. The value of \( \alpha_S(M_Z) \) was determined by fitting NLO QCD predictions to the \( d\sigma/dE^\text{jet}_T \) distribution [6]. The fit obtained with the \( k_T \) algorithm yielded:\n\[
\alpha_S(M_Z) = 0.1206^{+0.0023}_{-0.0022}(\text{exp.})^{+0.0042}_{-0.0035}(\text{th.})
\]
The value is in good agreement with the world and HERA averages and the errors are comparable to those of other recent measurements.

The energy scale dependence of \( \alpha_S \) was determined from NLO QCD fits without assuming the running of \( \alpha_S \) [6]. The result, shown in fig. 5 demonstrates the running of \( \alpha_S \) over a large range in \( E^\text{jet}_T \). The predicted running calculated in two loops [13] is in good agreement with the data.

6 Summary

Inclusive-jet photoproduction was measured with the ZEUS detector at the \( ep \) collider HERA. Cross sections were calculated as functions of \( E^\text{jet}_T \) and \( \eta^\text{jet} \). In general they are well described by NLO QCD predictions. Three jet algorithms were studied with respect to the comparison of data and predictions showing that the observed differences are small. Studies of multi-parton interactions have shown that their inclusion improves the description of the jet rates at low \( E^\text{jet}_T \) and high \( \eta^\text{jet} \). The measured cross sections have the potential to improve PDFs of photon and proton when included in a global fit. The strong coupling constant \( \alpha_S \) was determined at the mass of the Z boson and energy scaling was observed over a wide range of \( E^\text{jet}_T \).
Figure 5: Dependence of $\alpha_S$ on $E_{T}^{\text{jet}}$ as scaling variable. Solid line: normalisation group prediction. Error bars: uncorrelated experimental errors. Shaded band: correlated experimental errors. Hatched band: correlated experimental and theoretical errors added in quadrature.
