Abstract

Supersymmetric Grand Unified Theories often involve an additional Abelian group factor apart from the standard model hypercharge. Although in many cases there is a procedure to avoid loop-induced mixing of the gauge kinetic terms by choosing a suitable basis for the two $U(1)$ groups in group space, a residual mixing in the soft SUSY breaking gaugino mass terms remains. In this letter we generalize the renormalization group equations for the gaugino mass terms to account for this effect. In a further calculation we also present the necessary adjustments in the renormalization group equations of the trilinear soft breaking couplings and the soft breaking scalar mass squares.
The renormalization group equations (RGEs) describe the dependence of the coupling constants on the choice of the renormalization scale $\mu$, which is commonly translated into an energy dependence, as the perturbative series usually converges best if one chooses $\mu$ to be of the order of the characteristic energy scale of a given process. In supersymmetric model building [12] these equations constitute the framework which is employed to derive the potential unification of the gauge interactions into one fundamental force (GUT). They also describe the evolution of all other Lagrangian parameters - including the soft supersymmetry breaking parameters mediated to the “visible” sector through some mechanism at high scales - from a high unification scale down to the energy scales accessible to current collider experiments.

The RGEs for a supersymmetric model with an arbitrary semi-simple gauge group – only subject to the constraint that it does not contain a product of several $U(1)$ gauge groups – were given in [3]. We present a way of treating the case with two Abelian gauge groups, including a consistent generalization of the one-loop RGEs from [3] in the case, where a mixing of gauge kinetic terms at the tree-level does not occur, i.e.

$$\kappa F_{\mu\nu}^i F_{\mu\nu,j}^\prime = 0 \quad \forall i \neq j.$$  \hspace{1cm} (1)

In this situation we will show that the general concept presented in [4,5], where an additional coupling parametrizing the mixing is introduced, can be simplified considerably by an appropriate choice of basis for the $U(1)$ groups.

First, we specify the type of models in which condition (1) holds, i.e. where our formalism is applicable: Consider some potentially multi-scale symmetry breaking scenario:

$$\mathcal{G}_N^{(0)} \rightarrow \mathcal{G}_N^{(1)} \times U(1)^2 \rightarrow \text{SM},$$  \hspace{1cm} (2)

where $\mathcal{G}_N^{(0)}$ denotes a simple Lie group of rank $N$ and $\mathcal{G}_N^{(1)}$ an arbitrary semi-simple non-Abelian subgroup of it. This implies, that condition (1) holds at $\Lambda$ for all $U(1)$ groups in $\mathcal{G}_N^{(1)} \times U(1)^2$, as they all originate from non-Abelian gauge multiplets above $\Lambda$. A term as in Eq. (1) would have to necessarily arise from a matching condition at scale $\Lambda$

$$\kappa G_{\mu\nu,1} C_{\mu\nu,2} \rightarrow \kappa' F_{\mu\nu,1} F_{\mu\nu,2},$$  \hspace{1cm} (3)

with $G_{\mu\nu}$ being a non-Abelian field-strength tensor, which itself is not gauge invariant, so the left-hand side of Eq. (3) is forbidden by the gauge symmetry.

Our argumentation holds if there are intermediate symmetry breaking steps above $\Lambda$, with arbitrary semi-simple gauge groups, as long as the rank $N$ is preserved. At the tree-level, there cannot appear mixing terms in the course of symmetry breaking, for the same reason as in Eq. (3). Furthermore all quantum corrections to $\kappa'$ in any intermediate phase vanish, as the original rank $N$ is preserved, implying that the matter content has to form complete multiplets of $\mathcal{G}_N^{(0)}$. Hence, the trace over complete representations of the full GUT group vanish for products of different generators:

$$\text{tr}[T^A T^B] = 0 \quad \forall A \neq B.$$  

At the low breaking scale $\Lambda$, the rank of the gauge group is reduced, relaxing the requirement for the matter to come in complete irreducible representations of $\mathcal{G}_N^{(0)}$. Therefore, a mixing among the $U(1)$ gauge-kinetic terms may be induced via quantum corrections from matter of representations made incomplete by the symmetry breaking. Typical examples for such scenarios can be found in [6,7] and arise e.g. in GUT breaking chains like $E_6 \rightarrow SO(10) \times U(1)$ or $E_6 \rightarrow SU(5) \times U(1)^2$. 

1
We will now develop a scheme for constructing the basis for the two $U(1)$ gauge groups, such that the mixing induced at the one-loop level can be avoided in the $G_{N-d}^{(3)}_{d \geq 3} \times U(1)^2$ phase.

At $\Lambda$, we demand the gauge covariant derivatives in two adjacent phases to be equal:

$$D_{\mu}^A \bigg|_{\Lambda} = D_{\mu}^{A+1} \bigg|_{\Lambda}.$$  \hspace{1cm} (4)

From this we obtain a system of linear equations for the couplings and the charges of the new gauge group as functions of the corresponding parameters of the mother group:

$$g^A Q^A = \lambda_1^A g_1 Q_1 + \lambda_2^A g_2 Q_2 + \lambda_3^A g_3 Q_3,$$

$$g^B Q^B = \lambda_1^B g_1 Q_1 + \lambda_2^B g_2 Q_2 + \lambda_3^B g_3 Q_3,$$

$$g^C Q^C = \lambda_1^C g_1 Q_1 + \lambda_2^C g_2 Q_2 + \lambda_3^C g_3 Q_3.$$  \hspace{1cm} (5)

Here, $U(1)^A \times U(1)^B$ are the remaining unbroken groups in $G_{N-d}^{(3)}_{d \geq 3} \times U(1)^2$, and $U(1)^C$ corresponds to the broken Cartan generator of the non-Abelian gauge group, respectively. In Eq. (5) there are 15 free parameters $\{g^a, Q^a, \lambda_a^a\}$ which can be uniquely determined (up to signs) by applying the following twelve constraints:

1. The vacuum expectation value breaking the symmetry at scale $\Lambda$ is not charged under both unbroken $U(1)$ groups:

$$Q^a \langle H_\Lambda \rangle = 0 \quad \text{for } a = A, B;$$

2. The broken and unbroken generators are normalized according to the Dynkin index of the full GUT representation $R$, $S(R)$ (no summation over $a$):

$$\sum_{i \in R} Q^a_i Q^a_i = S(R) \quad \text{for } a = A, B, C;$$

3. Vanishing mixing at the one-loop level:

$$\text{tr}_R [Q^A Q^B] \equiv \sum_{i \in R} Q^A_i Q^B_i = 0$$

4. Corresponding transformations of the gauge fields are orthogonal:

$$(A^A_\mu, A^B_\mu, A^C_\mu) = (A^A_\mu, A^B_\mu, A^C_\mu) \lambda^T, \quad \text{with } \lambda_a^a \lambda_b^b = \delta_{ij}.$$  \hspace{1cm} (6)

A suitable framework to construct the charge operators in Eq. (5) is the concept of projection matrices in the weight space of the gauge groups, as presented in [8]. The representations to sum over in the constraints 2. and 3. as well as the field with non-trivial vacuum expectation value breaking the symmetry in constraint 1. can then be represented by their corresponding weights.

Applying this procedure at the scale where the rank of the gauge group is reduced for the first time in the chain of symmetry breakings ensures that there does not occur any mixing among gauge-kinetic terms at the one-loop level. If there are subsequent symmetry breaking mechanisms leading again to two Abelian gauge groups, the procedure can be applied repeatedly. The advantage of this scheme is, that one can still apply the RGEs as given in [3] for gauge and superpotential couplings without any changes.

---

1For the unbroken $U(1)$ groups below the scale $\Lambda$, one can also sum over complete multiplets $R$ of $G_{N}^{(0)}$, as the charges of the particles that have been integrated out in the symmetry breaking step have to be zero under the unbroken groups.
Although, by this procedure one can avoid a mixing in the gauge kinetic term, a remnant shows up for softly broken supersymmetric models, unless the corresponding gaugino masses at the breaking scale are degenerate, as
\[ \mathcal{L}_{M} = \tilde{\chi}_i M_{ii} \bar{\chi}_i = \tilde{\chi}^a \chi^a M_{ij} \bar{\chi}^b \bar{\chi}^b \Rightarrow M^{ab} \neq \text{diag}, \quad \text{unless } M_{ii} \equiv M \forall i \] (7)

At first glance, non-degenerate gaugino masses seem rather artificial (though the SUSY-breaking mechanism might not be completely $U(1)$-blind). Note however, that they naturally appear in the multi-scale models mentioned above, as $U(1)$ gaugino masses can evolve differently between intermediate scale above $\Lambda$, as well as in SUSY-breaking mechanisms sensitive to the beta function of the gauge group under consideration like AMSB [9]. Another example where non-degenerate gaugino mass terms could arise are mixed mediation mechanisms like e.g. mirage mediation [10].

In the following, we will present the generalized RGEs in the DR scheme [11] at the one-loop level for soft SUSY breaking terms, accounting for this effect. We use the conventions and nomenclature of [3]. In the absence of $U(1)$ mixing the one-loop RGEs for the soft-breaking gaugino masses are given by [3]
\[ \frac{d}{dt} M_a = \frac{2}{16\pi^2} \beta_a g_a^2 M_a, \] (8)
with
\[ \beta_a = S(R) - 3C(G), \] (9)
where $S(R)$ is the Dynkin index summed over all chiral superfields, and $C(G)$ the quadratic casimir of the adjoint representation, respectively. The logarithm of the ratio of scales is denoted as $t = \log \mu/\mu_0$. In the presence of gaugino mass mixing terms, we have to extend Eq. (8) in order to describe the running of the full gaugino mass matrix:
\[ \frac{d}{dt} M_{ab} = \frac{1}{16\pi^2} (\beta_a g_a^2 M_{ab} + \beta_b g_b^2 M_{ab}). \] (10)

These contributions arise from the following diagrams

Note, that the running of the diagonal entries in the gaugino mass matrix are not altered in the presence of mixed mass terms, as diagrams like

are by construction canceled out after rotating to the new $U(1)$ basis.
Besides this effect on the running of the full gaugino mass matrix, there is also a modification of the RGEs for the trilinear soft breaking parameters by non-diagonal gaugino mass terms. The new diagrams contributing to the running of the trilinear terms are of the form:

\[
\frac{dh^{ijk}}{dt} \supset M_{ab} \,,
\]

The corresponding renormalization group equations for the soft trilinear terms now read

\[
\frac{dh^{ijk}}{dt} = \frac{1}{16\pi^2} \left[ \frac{1}{2} h^{ijl} Y_{lpq} Y^{pqk} + Y^{ijl} Y_{lpq} h^{pqk} + 2 \left( \delta_{ab} h^{ijk} - 2 M_{ab} Y^{ijl} \right) g_a g_b C_{ab}(k) \right] + (k \leftrightarrow i) + (k \leftrightarrow j),
\]

with

\[
C_{ab}(k) = \begin{cases} C_a(k) & \text{if } a = b \\ Q_a^k Q_b^k & \text{if } a \neq b \end{cases}.
\]

The first line has to be applied for non-Abelian and diagonal U(1) groups, while the second line accounts for mixing U(1) factors.

Finally, for the scalar mass squared terms, the generalization of the RGE result calculated in [3], adjusted to take U(1) mixing into account, reads:

\[
\frac{d(m^2)^i_j}{dt} = \frac{1}{16\pi^2} \left[ \frac{1}{2} Y^{ijp} Y^{pmn}(m^2)^i_n + \frac{1}{2} Y^{ipq} Y^{pmn}(m^2)^p_n + 2 Y^{ijp} Y^{pnm}(m^2)^j_n \\
+ h_{jnp} h^{ipq} - 8\delta^i_j |M_{ab}|^2 g_a g_b C_{ab}(j) + 2 g_a^2 \delta^i_j Q_a^k \left( \delta^k_j Q_b^k(m^2)^n_j \right) \right],
\]

where in the last term the index \( \beta \) runs over all U(1) factors.

**Conclusions:**

In this letter, we studied a class of supersymmetric GUT models, where U(1) mixing forbidden at tree-level can occur at the (one-)loop level and defined a generic matching scheme for the couplings at intermediate thresholds by constructing a suitable choice of basis. Such a basis avoids the mixing of the gauge couplings and completely diagonalizes the U(1) vector superfields in the absence of gaugino mass non-degeneracy. In that case, using this specific basis allows to use the setup in [3] without any changes. In phenomenologically interesting GUT models, however, gaugino masses at some high or intermediate scale could be non-degenerate, mostly by means of running or through some explicit construction. For such a case, gaugino masses can not longer be simultaneously diagonalized. Consequently, we gave the modifications for the renormalization group equations for the gaugino masses, the trilinear soft breaking terms and the sfermion soft mass squared terms at the one-loop order.
