Measurement of the Neutral Current DIS Cross Section at H1

Nataša Raičević
University of Montenegro
on behalf of the H1 Collaboration

2007 Europhysics Conference on High Energy Physics
Manchester 19th - 25th July, 2007
In 2000-2002 HERA-I ($E_p = 820, 920$ GeV) upgraded to HERA-II ($E_p = 920$ GeV)

- Increased luminosity
- Polarised leptons

Since April 2007 until the end of June

- Low energy run ($E_p = 460$ GeV)
- Intermediate energy run ($E_p = 575$ GeV)
**Neutral Current (NC) $e^\pm p$ Deep Inelastic Scattering (DIS)**

\[
e^\pm + p \rightarrow e'^\pm + X
\]

Virtuality of exchanged boson: $Q^2 = -q^2 = -(k-k')^2$

Fraction of proton momentum carried by struck quark: $x = Q^2/(2p \cdot q)$

Fraction of energy transferred from incoming lepton at proton rest frame $y = (p \cdot q)/(p \cdot k)$

\[\gamma - p\text{ invariant mass } W = \sqrt{Q^2(1-x)/x}\]

Kinematics can be reconstructed using scattered lepton (e') or hadronic final state.

\[\tilde{\sigma}_{NC}(x, Q^2) - \text{NC reduced cross-section}\]

\[
\frac{d^2\sigma_{NC}(e^\pm p)}{dx dQ^2} = \frac{2\pi\alpha^2}{xQ^4} \left[ Y_+ \left( \tilde{F}_2 - \frac{Y_+^2}{Y_+} \tilde{F}_L + \frac{Y_-}{Y_+} x \tilde{F}_3 \right) \right]
\]

\[Y_\pm = 1 \pm (1 - y)^2\]

\[
\text{dominant contribution} \quad \text{important only at high } Q^2 \quad \text{sizable contribution for high } y
\]
Structure Functions

Leading order relations:

$$F_2 = \sum e_q^2 (x_q + x\bar{q}) \quad xF_3 = 2\sum e_q a_q (x_q - x\bar{q}) \quad F_L = 0$$

In perturbative QCD: $F_L \sim a_s \cdot xg(x,Q^2)$

DIS one of the best tools to:

- Test the theory - validity of the DGLAP evolution
- Study proton internal structure - quark, anti-quark and gluon distribution PDFs: $xq(x,Q^2)$, $x\bar{q}(x,Q^2)$, $xg(x,Q^2)$
- NC DIS good probe of electro-weak dynamics
Scaling violations are well described over 4 orders of magnitude in $x$ and $Q^2$.

Precision ~ 2-3 % in the bulk region.
Cross section measurements provide input for the PDF fits.

Sea and gluon distributions are divided by a factor of 20.

There are still additional data and place for improvements in precision. H1 is working hard on this.
Ongoing NC analysis at H1

Measurements from HERA-I data only

- Domain of low $Q^2$
  $(10 \leq Q^2/\text{GeV}^2 \leq 150)$
  DGLAP evolution, PDFs with the highest precision - new result expected soon (down to 1% precision)

- Lowest $Q^2$ domain ($Q^2 \leq 10 \text{ GeV}^2$)
  Transition to non-perturbative region
  Phenomenological models
  NEW PRELIMINARY RESULT

Measurements from HERA-I+HERA-II

- High $Q^2$ domain ($Q^2 \geq 200 \text{ GeV}^2$)
  Polarisation effects and structure funct. - new result from the total data sample collected at H1 expected soon

- High $y$ domain ($y > 0.6$) - Sensitivity to $F_L$
  - low $Q^2$ - NEW PRELIMINARY RESULT
  - medium $Q^2$ - NEW PRELIMINARY RESULT
H1 analysis well on their way to provide the highest precision measurement of the proton structure

- Proton structure described by precise PDFs needed for making accurate predictions for any process involving protons.
- DGLAP QCD evolution provides $Q^2$ dependence of the PDFs $\to x$ dependence must come from data.

HERA covers the most important region for the LHC $W$, $Z^0$ cross section prediction.
Lowest $Q^2$ analysis from H1

High precision in the lowest $Q^2$ regime obtained via special runs:

- **MB** - Minimum Bias runs (high trigger rate)
- **SVX** - shifted interaction vertex (increase acceptance at lowest $Q^2$)
Reduced cross section measurement at lowest $Q^2$

New preliminary results obtained by combining three data sets:

- MB data from 1999
  $L = 2.1 \text{ pb}^{-1}, 0.5 \leq Q^2/\text{GeV}^2 \leq 12$

- Shifted vertex data from 2000
  $L = 504 \text{ nb}^{-1}, 0.2 \leq Q^2/\text{GeV}^2 \leq 3.5$

- MB data from 1997
  $L = 1.8 \text{ pb}^{-1}, 1.5 \leq Q^2/\text{GeV}^2 \leq 12$

Combined datasets $\rightarrow$ 2-3% precision

$$
\sigma_r(x, Q^2) = F_2(x, Q^2) - \frac{y^2}{1 + (1 - y)^2} F_L(x, Q^2)
$$
Effective $\gamma^* p$ cross section at lowest $Q^2$

\[
F_2 = \frac{Q^2}{4\pi^2 a} (1-x)(\sigma_L + \sigma_T) \quad \text{at low } Q^2
\]

\[
F_L = \frac{Q^2}{4\pi^2 a} (1-x)\sigma_L
\]

\[
\sigma_{\gamma p}^{\text{eff}} = \sigma_T + \left[1 - y^2/(1 + (1-y)^2)\right]\sigma_L
\]

- Data fill the transition region at $Q^2 \sim 1 \text{ GeV}^2$
- New preliminary H1 measurements in agreement with ZEUS

Precision for $Q^2 > 5 \text{ GeV}^2$ reaches 1.5%
Raise of $F_2$

$$\sigma_r(x,Q^2) = c(Q^2)x^{-\lambda(Q^2)} - \frac{y^2}{y_+^2} F_L(Q^2)$$

$F_2(x,Q^2)$ at low $x$ ($<0.01$)

Extraction of $F_L$ at high $y$

$$F_L(x,Q^2) = F_2(x,Q^2) \cdot R/(1+R)$$
For kinematic reconstruction electron method is used

\[ y = 1 - \frac{E_e'}{E_e} \sin^2(\theta_e/2) \]

To reach high \( y \) with low and medium \( Q^2 \)
\[ \Rightarrow \text{as low as possible } E'_e \text{ required} \]

Good sample to study experimental conditions for the \( F_L \) measurement

Two analysis at H1 in parallel:

- High \( y \) analysis at low values of \( Q^2 \): \( L \approx 96 \text{ pb}^{-1} \)
- High \( y \) analysis at medium values of \( Q^2 \): \( L \approx 315 \text{ pb}^{-1} \)

Luminosities of \( e^+p \) and \( e^-p \) samples nearly symmetric
High $y$, low $Q^2$ analysis with HERA-II data

**Analysis strategy**

- At high $y$ there is a large photoproduction background in which hadronic final state can mimic the signature of the scattered lepton with low energy.

- Scattered lepton is identified by a cluster from SpaCal linked to a track in the Central Tracker (CT) which is used to measure its momentum and identify its charge from the sign of ratio of energy and momentum.

Background estimated using lepton candidates associated with wrong sign tracks. Charge symmetric lepton beam sample eliminates calorimeter response induced by background charge asymmetry.
Control plots

\[ E - p_z = (E - p_z)_{\text{HFS}} + (E - p_z)_{e'} = 2 \cdot \text{(measured beam energy)} \]
**High y cross section at low $Q^2$**

At $y = 0.825$

- About factor of 2 improvement in total uncertainty and about factor of 3 improvement in statistical uncertainty versus published results from HERA-I.
High $\gamma$, medium $Q^2$ analysis with HERA-II data

- Cluster required in LAr calorimeter
- Background subtraction procedure as for the low $Q^2$ region

Control plots
High $y$ cross section at medium $Q^2$

![Graph showing cross section data with different error bars and data points for $H1$.]

- Statistical errors significantly improved and phase space extended with respect to the published measurements.
H1 data from $e^+p$ from reduced proton beam energy

Since March 2007 - proton beam energies reduced

- $L \approx 13 \text{ pb}^{-1}$ at lowest $E_p = 460 \text{ GeV}$
- $L \approx 7 \text{ pb}^{-1}$ at intermediate $E_p = 575 \text{ GeV}$
Direct measurement of $F_L$ at HERA

$$\sigma_r(x,Q^2) = F_2(x,Q^2) - \frac{Y^2}{Y^+} F_L(x,Q^2)$$

Direct measurement of $F_L$ can be obtained by measuring $\sigma_r$ at the same $x$, $Q^2$ for different beam energies.

- Precise measurement of $F_L$ will provide constraints on the gluon contribution which are complementary to that obtained from the scaling violations of $F_2$ assuming DGLAP evolution.

- Direct $F_L$ measurement will allow to distinguish between different PDF fits.
Summary and Outlook

- New preliminary results on Neutral Current DIS cross section from H1 at
  - lowest $Q^2$ domain,
  - high $y$, low $Q^2$ domain,
  - high $y$, medium $Q^2$ domain.

- 2-3% precision of HERA measurements is reached in the region important for $W$, $Z$, $H$ cross section prediction at the LHC. Next step is 1-1.5% precision from H1.

- Direct measurements of the $F_L$ structure function using data with different proton beam energies will be important check of the theory and will put new constraints on the gluon density.
