Key words Supersymmetry, MSSM, squarks, flavour violation, LHC

We study the effect of squark generation mixing on squark production and decays at the LHC in the Minimal Supersymmetric Standard Model (MSSM). We show that the effect can be very large despite the very strong constraints on quark flavour violation (QFV) from experimental data on B mesons. We find that the two lightest up-type squarks $\tilde{u}_1, \tilde{u}_2$ can have large branching ratios for the decays into $c\tilde{\chi}_1^0$ and $t\tilde{\chi}_1^0$ at the same time, leading to QFV signals $pp \to cl (tc) + \text{missing-}E_T + X$ with a significant rate. The observation of this remarkable signature would provide a powerful test of supersymmetric QFV at LHC. This could have a significant impact on the search for squarks and the determination of the underlying MSSM parameters.

1 Introduction

The Minimal Supersymmetric Standard Model is the most intensively studied extension of the Standard Model (SM) of elementary particles. Low energy Supersymmetry (SUSY) provides a solution to the so-called hierarchy problem in the Higgs sector, allows gauge coupling unification, and provides possible candidates for the dark matter observed in our Universe. If the MSSM is realized in nature, LHC will copiously produce gluinos and squarks, the supersymmetric partners of gluons and quarks, for masses of $O(1 \text{ TeV})$. However, even if SUSY is discovered, it will be still a long way to determine the parameters of the underlying model, which would shed light on the mechanism of SUSY breaking. So-called soft-SUSY-breaking terms are introduced in the SUSY Lagrangian. As these soft-SUSY-breaking terms could also be the source of flavour violation beyond the Standard Model (SM), the measurement of flavour violating observables is directly linked to the crucial question about the SUSY-breaking mechanism. It is usually assumed that production and decays of squarks are quark-flavour conserving (QFC). However, additional flavour structures (i.e. squark generation mixings) would imply that squarks are not quark-flavour eigenstates, which could result in sizable quark-flavour violation (QFV) effects significantly larger than those due to the Cabibbo-Kobayashi-Maskawa (CKM) mixing. In this contribution we study the effect of QFV due to the mixing of charm-squarks and top-squarks on production and decays of squarks at the LHC in the general MSSM.

2 Squark mixing with flavour violation and constraints

The most general up-type squark mass matrix including left-right mixing as well as quark-flavour mixing in the super-CKM basis of $\tilde{u}_{\alpha\beta} = (\tilde{u}_L, \tilde{c}_L, \tilde{t}_L, \tilde{u}_R, \tilde{c}_R, \tilde{t}_R), \gamma = 1, \ldots, 6$, is [1]
We define dimensionless QFV parameters for a unitary transformation $R$. Eberl, A. Bartl, B. Herrmann, K. Hidaka, W. Majerotto, and W. Porod: Squark generation mixing at LHC and theoretical constraints, for details see [1]:

The physical mass eigenstates $\tilde{u}_i$, $i = 1, \ldots, 6$, are given by $\tilde{u}_i = R^u u_0$. The mixing matrix $R^u$ and the mass eigenvalues are obtained by a unitary transformation $R^u M^u R^u \dagger = \text{diag}(m_{\tilde{u}_{1}}, \ldots, m_{\tilde{u}_{6}})$, where $m_{\tilde{u}_{i}} < m_{\tilde{u}_{j}}$ for $i < j$.

We define dimensionless QFV parameters $\delta_{\alpha\beta}^{uLL}$ and $\delta_{\alpha\beta}^{uRR}$ as

$$
\delta_{\alpha\beta}^{uLL} \equiv M^u_{Q123}/\sqrt{M^2_{Q1}\cdot M^2_{Q23}}, \quad \delta_{\alpha\beta}^{uRR} \equiv M^u_{U123}/\sqrt{M^2_{U12}\cdot M^2_{U23}},
$$

for $\delta_{\alpha\beta}^{uRL}$ see [1]. For example, $\delta_{23}^{uLL}$ and $\delta_{23}^{uRR}$ are the $\tilde{c}_L - \tilde{t}_L$ and $\tilde{c}_R - \tilde{t}_R$ mixing parameters. In our analysis, we impose the following conditions on the MSSM parameter space in order to respect experimental and theoretical constraints, for details see [1]:

i) Constraints from the B-physics experiments [2], such as $2.92 \times 10^{-4} < B(b \to s \gamma) < 4.22 \times 10^{-4}$, $|\Delta M^S_{B_{s}} - 17.77| < 3.31 \text{ ps}^{-1}$ and those from other rare B-decays

ii) The experimental limit on the SUSY contributions to the $\rho$ parameter

iii) LEP and Tevatron lower limits on the SUSY particle masses

iv) Vacuum stability conditions for the elements of the trilinear coupling matrices $T_U$ and $T_D$

The conditions i) and iv) strongly constrain the 2$^{nd}$ and 3$^{rd}$ generation squark mixing parameters $M^2_{Q23}$, $M^2_{D23}$, $T^2_{U23}$, $T^2_{D23}$, and $T^2_{D32}$, but not $M^2_{U23}$ which is parametrized by $\delta_{23}^{uRR}$. In the following numerical presentation all of these constraints are fulfilled.

### 3 Flavour violating fermionic squark decays at LHC

First we study the effect of the mixing between the 2$^{nd}$ and 3$^{rd}$ generation of up-squarks on their decays only. The widths of the two–body decays

$$
\tilde{u}_i \to u_k \tilde{g}, \ u_k \tilde{\chi}_n^0, \ d_k \tilde{\chi}_m^+, \ \tilde{u}_j Z^0, \ \tilde{d}_j W^+, \ \tilde{\chi}_j^0
$$

are calculated, where $u_k = (u, c, t)$ and $d_k = (d, s, b)$. A specific numerical scenario is chosen so that QVF signals at LHC are large. It is given in Table[1]. In this scenario one has $\delta_{23}^{uLL} = 0.008$, $\delta_{23}^{uRR} = 0.4$ and $\delta_{23}^{uRL} = \delta_{23}^{uLR} = 0.6$ for the QVF parameters. We obtain (masses in GeV):

$m_{\tilde{u}_{1}} = 472, m_{\tilde{u}_{2}} = 708, \tilde{u}_{1} \sim -0.72 \tilde{c}_R + 0.70 \tilde{t}_R, \tilde{u}_{2} \sim 0.70 \tilde{c}_R + 0.71 \tilde{t}_R, m_{\tilde{c}_1} = 138;\text{ and the branching ratios } B(\tilde{u}_{1} \to c\tilde{\chi}_1^0) = 0.59, B(\tilde{u}_{2} \to t\tilde{\chi}_1^0) = 0.39, B(\tilde{d}_{1} \to c\tilde{\chi}_1^0) = 0.44, B(\tilde{d}_{2} \to t\tilde{\chi}_1^0) = 0.40.$

Note that the branching ratios of the decays of a squark into quarks of different generations are very large.
Table 1  Input parameters for the reference scenario (mass parameters in GeV). All $T_{U\alpha\beta}$ and $T_{D\alpha\beta}$ are zero.

![Diagram showing contours of QFV decay branching ratios](image)

Fig. 1  Contours of QFV decay branching ratios (a) $B(\tilde{t}_1 \rightarrow c\tilde{\chi}_1^0)$ and (b) $B(\tilde{u}_1 \rightarrow t\tilde{\chi}_1^0)$ in the $(\Delta M_U^2, M_{U23}^2)$ plane.

simultaneously, which could lead to large QFV effects. In our scenario this is a consequence of the fact that both squarks $\tilde{u}_{1,2}$ are mainly strong mixtures of $\tilde{c}_R$ and $\tilde{t}_R$ due to the large $\tilde{c}_R - \tilde{t}_R$ mixing term $M_{U23}^2 = (373 \text{ GeV})^2$ and that $\tilde{\chi}^0_1$ is mainly the $U(1)$ gaugino. This also suppresses the couplings of $\tilde{u}_{1,2}$ to $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0$ which are mainly $SU(2)$ gauginos. Note that $\tilde{\chi}_3^0$ and $\tilde{\chi}_2^0$ are very heavy in this scenario.

Fig. [I] shows the contours of $B(\tilde{u}_1 \rightarrow c\tilde{\chi}_1^0)$ and $B(\tilde{u}_1 \rightarrow t\tilde{\chi}_1^0)$ in the $(\Delta M_U^2, M_{U23}^2)$ plane with $\Delta M_U^2 \equiv M_{U22}^2 - M_{U33}^2$. The range of $M_{U23}^2$ shown corresponds to the range $|\delta_{23}^{RR}| < 0.45$ for $\Delta M_U^2 = 0$. In all plots the point corresponding to the scenario given in Table I is marked by an "x". We see that there are sizable regions where both decay modes are important at the same time. The observed behavior can be easily understood in the limit where the $\tilde{t}_L - \tilde{t}_R$ mixing is neglected since in this limit only the mixing between $\tilde{c}_R$ and $\tilde{t}_R$ is relevant for $\tilde{u}_{1,2}$ and the corresponding effective mixing angle is given by $\tan(2\theta_{\tilde{c}_R\tilde{t}_R}) \equiv 2M_{U23}^2/(\Delta M_U^2 - m_t^2)$. Note that for $\Delta M_U^2 - m_t^2 > 0$ [\Delta M_U^2 - m_t^2 < 0], we have $\tilde{u}_1 \sim \tilde{c}_R$ [\tilde{c}_R (\sim \tilde{t}_R)]. We further study effects of the squark generation mixing on QFV signals at LHC. The large $B(\tilde{u}_i \rightarrow c\tilde{\chi}_1^0)$ and $B(\tilde{u}_i \rightarrow t\tilde{\chi}_1^0)$ ($i = 1, 2$) may result in a sizable rate for the following QFV signals:

$$p p \rightarrow \tilde{u}_{1,2} \tilde{u}_{1,2} X \rightarrow c \tilde{t} \tilde{c}_R \tilde{c}_R \tilde{\chi}_1^0 \tilde{\chi}_1^0 X, \ t \tilde{c}_R \tilde{\chi}_1^0 \tilde{\chi}_1^0 X,$$

where $X$ contains only beam jets and the $\tilde{\chi}_1^0$'s give rise to missing transverse energy $E_T^{\text{miss}}$. Defining

$$\sigma_{\tilde{u}_i}^{\tilde{u}_i} \equiv \sigma(p p \rightarrow \tilde{u}_i \tilde{u}_j X) \times (B(\tilde{u}_i \rightarrow c\tilde{\chi}_1^0)) \times (B(\tilde{u}_j \rightarrow t\tilde{\chi}_1^0)) + B(\tilde{u}_i \rightarrow t\tilde{\chi}_1^0) \times (B(\tilde{u}_j \rightarrow \tilde{\chi}_1^0)),$$

where $X$ contains only beam jets and the $\tilde{\chi}_1^0$'s give rise to missing transverse energy $E_T^{\text{miss}}$. Defining

$$\sigma_{\tilde{u}_i}^{\tilde{u}_i} \equiv \sigma(p p \rightarrow \tilde{u}_i \tilde{u}_j X) \times (B(\tilde{u}_i \rightarrow c\tilde{\chi}_1^0)) \times (B(\tilde{u}_j \rightarrow t\tilde{\chi}_1^0)) + B(\tilde{u}_i \rightarrow t\tilde{\chi}_1^0) \times (B(\tilde{u}_j \rightarrow \tilde{\chi}_1^0)),$$

where $X$ contains only beam jets and the $\tilde{\chi}_1^0$'s give rise to missing transverse energy $E_T^{\text{miss}}$. Defining

$$\sigma_{\tilde{u}_i}^{\tilde{u}_i} \equiv \sigma(p p \rightarrow \tilde{u}_i \tilde{u}_j X) \times (B(\tilde{u}_i \rightarrow c\tilde{\chi}_1^0)) \times (B(\tilde{u}_j \rightarrow t\tilde{\chi}_1^0)) + B(\tilde{u}_i \rightarrow t\tilde{\chi}_1^0) \times (B(\tilde{u}_j \rightarrow \tilde{\chi}_1^0)),$$
we obtain the following cross sections \( \sigma_{11} \equiv \sigma(pp \rightarrow \tilde{u}_1 \tilde{u}_1 X) \), \( \sigma_{11}^{11} \) and \( \sigma_{22}^{22} \equiv \sigma(pp \rightarrow \tilde{u}_2 \tilde{u}_2 X) \), \( \sigma_{22}^{22} \).

In Fig. 2 we show the \( \delta_{23}^{RR} \) dependences of the QFV production cross sections \( \sigma_{ii} \) (\( i = 1, 2 \)) at \( E_{cm} \) = 7 and 14 TeV, where all basic parameters other than \( M_{\tilde{u}_{12}} \) are fixed as in the scenario of Table [1]. The QFV cross sections at 14 TeV are about an order of magnitude larger than those at 7 TeV. We see that the QFV cross sections quickly increase with increase of the QFV parameter \( \delta_{23}^{RR} \) around \( \delta_{23}^{RR} = 0 \) and that they can be quite sizable in a wide allowed range of \( \delta_{23}^{RR} \). The mass of \( \tilde{u}_1 \) (\( \tilde{u}_2 \)) decreases (increases) with increase of \( \delta_{23}^{RR} \). This leads to the increase of \( \sigma_{11}^{11} \) and the decrease of \( \sigma_{22}^{22} \) with increase of \( \delta_{23}^{RR} \). \( \sigma_{11}^{11} \) vanishes for \( \delta_{23}^{RR} \gtrsim 0.76 \), where the decay \( \tilde{u}_1 \rightarrow t\chi_1^0 \) is kinematically forbidden. We have \( \tilde{u}_2 = \tilde{u}_R \) for \( \delta_{23}^{RR} \gtrsim 0.9 \), which explains the enhancement of \( \sigma(pp \rightarrow \tilde{u}_2 \tilde{u}_2 X) \) and the vanishing of \( \sigma_{22}^{22} \) for \( \delta_{23}^{RR} \gtrsim 0.9 \). We see that the expected number of signal events at the LHC would be up to about 20000 (10) for an integrated luminosity of 100 fb\(^{-1} \) (1 fb\(^{-1} \)) at \( \sqrt{s} = 14 \) TeV (7 TeV). Concerning the detectability, top-quark identification is necessary to distinguish the proposed signal from \( t\bar{t} \) production including missing energy. Efficient charm-tagging would be very helpful for detecting flavour mixing between the second and third generation. Otherwise, one should rather search for the signature jet + \( t \bar{t} \) + \( E_T^{miss} \) [1].

We remark that for the QFV scenarios based on a mSUGRA scenario such as SPS1a’ we have obtained results similar to the presented one [1].

In summary, despite the strong constraints from experimental data, non-minimal QFV can lead to new signatures at LHC. This has been shown explicitly for one scenario. The given conclusions hold, however, for a wide range of the MSSM parameter space [1]. Of course, the next necessary step is a detailed Monte-Carlo study including background reactions and detector simulation in order to identify the parameter region where the proposed QFV signal is observable with sufficient significance.
