The luminescence of Cu\(^+\) and Cu\(^{2+}\) ions in CsBr:Cu and CsBr:CuBr\(_2\) crystals, respectively, is investigated under excitation by synchrotron radiation in the CsBr fundamental absorption range at 10 K and 300 K. The existence of the luminescence bands of different origin: (i) the intrinsic radiative transition of Cu\(^+\) ions in the bands peaked at 2.61 eV and 2.23 eV, (ii) the recombination luminescence of Cu\(^{2+}\) ions in the bands peaked at 2.55 eV and 2.13 eV, (iii) the luminescence of excitons localized around Cu\(^+\) and Cu\(^{2+}\) ions in the band peaked at 3.08 eV and 3.38 eV, respectively, was found in CsBr:Cu and CsBr:CuBr\(_2\) crystals. The energies of creation of exciton localized around Cu\(^+\) and Cu\(^{2+}\) ions were determined.

1. Introduction

Copper ions in different charge states usually create the set of strongly localized states in ionic compounds [1]. This, in principle, may be used for development of the storage phosphors, working on the principle of photostimulated luminescence (PSL), and materials for thermoluminescent (TL) dosimetry [2]. The luminescence of Cu\(^{2+}\) ions in CsBr:Cu crystal under the excitation of bands related to creation of excitons in the range of high-energy absorption band related to partly allowed \(1A\_g \rightarrow 1T\_2g\) transition of Cu\(^{2+}\) ions [3, 4, 6, 9], presents the complex emission band in the visible range as a superposition of the two main sub-bands peaked at 2.61 eV and 2.23 eV (Fig. 1a, curve 1). The dominant high-energy emission band corresponds to the \(1E \rightarrow A\_g\) radiation transitions [9]. In work [3] we also noted that as opposite to the typical one-component character of Cu\(^+\) emission [9], the luminescence spectrum of Cu\(^+\) ions in CsBr:Cu crystal under \(1A\_g \rightarrow 1T\_2g\) band excitation consists also of second low-energy emission band peaked at 2.23 eV. The small-intensity bands peaked approximately at 2.5 eV and 2.13 eV in the spectra of CsBr:Cu crystal most probably are related to the luminescence of Cu\(^{2+}\) ions.

3. Experimental results and discussion

3.1. Luminescence of Cu\(^+\) ions

The emission spectrum of the Cu\(^+\) ions in CsBr:Cu crystal at 300 K under excitation at 5.29 eV, in the range of high-energy absorption band related to partly allowed \(1A\_g \rightarrow 1T\_2g\) transition of Cu\(^{2+}\) ions [3, 4, 6, 9], presents the complex emission band in the visible range as a superposition of the two main sub-bands peaked at 2.61 eV and 2.23 eV (Fig. 1a, curve 1). The dominant high-energy emission band corresponds to the \(1E \rightarrow A\_g\) radiation transitions [9]. In work [3] we also noted that as opposite to the typical one-component character of Cu\(^+\) emission [9], the luminescence spectrum of Cu\(^+\) ions in CsBr:Cu crystal under \(1A\_g \rightarrow 1T\_2g\) band excitation consists also of second low-energy emission band peaked at 2.23 eV. The small-intensity bands peaked approximately at 2.5 eV and 2.13 eV in the spectra of CsBr:Cu crystal most probably are related to the luminescence of Cu\(^{2+}\) ions.

Under excitation by SR, in the exciton range of 6.04–6.88 eV, the emission spectrum of CsBr:Cu crystal at 300 K (Fig. 1a, curves 1, 2) and at 10 K (Fig. 1b,
Luminescence of Cu$^+$ and Cu$^{2+}$ Ions in CsBr Crystals

1. Emission spectra (normalized) of CsBr:Cu crystals at 300 K (a) and 10 K (b) under excitation by SR in the range of absorption bands of Cu$^+$ ions at 5.29 eV (1a), exciton range at 6.04 eV (2a) and range of interband transition at 6.88 eV (3a) and 6.67 eV (b).

Fig. 1. Emission spectra of Cu$^+$ luminescence in the band peaked at 2.69 eV (1) and 2.06 eV (2) at 300 K and luminescence of excitons localized around Cu$^{2+}$ ions in the band peaked at 3.13 eV (3) at 10 K in CsBr:Cu crystal. Absorption spectra of CsBr:Cu crystal (4) are shown for comparison.

3.2. Luminescence of Cu$^+$ ions

Fig. 2. Excitation spectra of Cu$^+$ luminescence in the band peaked at 2.69 eV (1) and 2.06 eV (2) at 300 K and luminescence of excitons localized around Cu$^{2+}$ ions in the band peaked at 3.13 eV (3) at 10 K in CsBr:Cu crystal. Absorption spectra of CsBr:Cu crystal (4) are shown for comparison.

The luminescence spectrum of Cu$^{2+}$ ions in CsBr:CuBr$_2$ crystal at 300 K, under excitation with an energy of 4.09 eV in the strong absorption band of this crystal caused by Cu$^{2+}$ dopant (Fig. 4, curve 3) [3, 4], consists of the dominant emission band of Cu$^{2+}$ ions peaked at 2.49 eV with low-intensity bump in the low-energy side (Fig. 3b, curve 1). Besides the emission band of Cu$^{2+}$ ions, under excitation of the CsBr:CuBr$_2$ crystal in the exciton range at 5.98 eV, we also observed two emission bands of Cu$^{2+}$ ions peaked at 2.71 eV and 2.55 eV (Fig. 1b, curve 2). The luminescence spectrum of CsBr$_2$ crystal under excitation at 6.76 eV in the fundamental absorption range presents the wide emission band peaked at 2.86 eV (Fig. 1b, curve 3). Probably, this band is a complex superposition of the emission of Cu$^+$ and Cu$^{2+}$ ions and the luminescence of excitons localized around Cu$^{2+}$ and partly Cu$^+$ ions.

More detailed separation of luminescence bands in CsBr crystals related to Cu$^{2+}$ doping can be done at 10 K (Fig. 3b). Under excitation by SR at 7.07 eV in the onset of interband transitions, the emission spectrum of CsBr:Cu crystals in UV (4.0–3.0 eV) range shows the dominant emission of self-trapped excitons (STE) in the band peaked at 3.53 eV and luminescence band of Cu$^{2+}$ ions at 2.55 eV in the visible range. Apart from the emis-
Fig. 3. Emission spectra (normalized) of CsBr:CuBr₂ crystals at 300 K (a) and 10 K (b) under excitation by SR in the range of Cu⁺ and Cu²⁺ ion absorption bands at 3.97 eV (1b) and 4.50 eV (1b), exciton range at 5.98 eV (2a) and in the interband transition range at 7.07 (3b) and 6.76 eV (3a).

Fig. 4. Excitation spectra (normalized) of Cu²⁺ luminescence in the band peaked at 2.25 eV (1a) at 300 K, and 2.53 eV (2b) and 2.15 eV (1b) at 10 K, and luminescence of excitons localized around Cu²⁺ ions in the band peaked at 3.26 eV (2a) at 300 K, and 3.44 eV (3b) at 10 K in CsBr:CuBr₂ crystal. Absorption spectrum of CsBr:CuBr₂ crystal (3a) is shown for comparison.

Emission of Cu²⁺ ions in the dominant band peaked at 2.55 eV and low-intensive band peaked at 2.13 eV, the luminescence of excitons localized around Cu²⁺ and Cu⁺ ions in the bands peaked at 3.38 and 3.10 eV appears also in the emission spectrum of CsBr:CuBr₂ crystals under excitation by SR with energies of 3.97 eV and 4.50 eV in the Cu²⁺ and Cu⁺ absorption bands (Fig. 3b, curve 1 and 2, respectively).

The excitation spectrum of the Cu⁺ luminescence in CsBr:CuB₂ crystals is very complicated (Fig. 4). The excitation spectrum of high-energy band of the Cu⁺ luminescence peaked at 2.55 eV at 300 K (Fig. 4a, curve 1) in CsBr transparency range consists of the intensive complex band peaked at 4.09 eV which coincides with the above mentioned strong absorption band of Cu²⁺ ions (Fig. 4a, curve 3). The fine structure of this band is observed at 8 K. Namely, this band at 8 K presents the superposition of three bands peaked at: 3.97, 4.20 and 4.59 eV (Fig. 4b, curve 2). In addition to these bands, other two high-energy bands peaked at 4.59 and 5.33 eV are also present in excitation spectrum of the Cu⁺ luminescence at 8 K. The excitation spectrum of the Cu²⁺ luminescence in the low-energy band peaked at 2.13 eV (Fig. 4b, curve 3) differs from that for high-energy band peaked at 2.55 eV mainly due to the overlapping of the excitation spectra of the first band with the excitation spectrum of low-energy band of the Cu⁺ luminescence (Fig. 2, curve 2). Specifically, the dominant sharp band peaked at 4.50 eV, most probably can be related exactly to the excitation band of Cu⁺ ions (Fig. 2b, curve 1). The band in the 5.0–5.2 eV range can be related to Cu⁰ ions [10].

The dominant band peaked at 5.99 eV in the excitation spectrum of the Cu²⁺ luminescence in CsBr₂ crystal at 300 K in the exciton range corresponds to the energy of formation of excitons bound with Cu²⁺ ions. The band peaked at 6.09 eV in the excitation spectrum of the luminescence in CsBr₂ crystal at 10 K in the exciton range corresponds to the energy of formation of excitons bound with Cu²⁺ ions. The intensive bands at 6.64 and 6.87 eV in the fundamental absorption range are related to excitation of the Cu²⁺ emission via e/h recombination.

4. Discussion and conclusions

The possible reasons for the existence of two bands of Cu⁺ and Cu²⁺ emission in CsBr crystal are as follows: (i) the existence of on- and off-centre configurations of the relaxed excited state of Cu⁺ and Cu²⁺ ions due to very large difference of the ionic radius of Cu⁺ and Cu²⁺ ions (0.77 Å and 0.73 Å, respectively) in sixfold coordi-
nation and Cs$^+$ cations (1.67 Å) [7], (ii) the formation of the dimer or other complex Cu$^+$ and Cu$^{2+}$ centers [6]. The existence of both considered models in Cu-doped alkali-halides has been discussed in works [6, 10–12]. In our opinion, both of these models can be realized also in CsBr:Cu and CsBr:CuBr$\_2$ crystals. The close form of excitation spectra for the low- and high-energy emission bands of Cu$^+$ ions (Fig. 2, curves 1 and 2) supports mainly the first mentioned model. At the same time, due to large concentration of copper dopant the formation of dimer centers is not excluded in the crystals under study. Very rich and complicated shape of the excitation spectra of the Cu$^{2+}$ luminescence and exciton luminescence of CsBr:CuBr$\_2$ crystals in the host transparency range (3.7–6.0 eV) and exciton range (6.0–7.2 eV) mostly supports the last assumption.

The spectral identification of all mentioned excitation bands of the Cu$^{2+}$ and Cu$^+$ luminescence in CsBr:Cu and CsBr:CuBr$\_2$ crystals presents the complicated task and will be performed in a separate paper. We only note here that the three bands (4.2–3.83 eV, 4.59 eV and 5.33 eV) in the excitation spectra of CsBr:Cu$^{2+}$ crystals at 10 K can be assigned to the CTT in the (CuBr$\_6$)$^{4\_}$ complexes formed in the alkali-halide crystals. The observed absorption and excitation spectra can be explained by taking into account the mixing of two $t_{1u}$ molecular orbitals of ligands which consist of $p_\pi$ and $p_\sigma$ halogen orbitals. The transitions in (CuX)$^{4\_}$ complexes from the ground $1E_g$ state to the excited $2T_{1u}\sigma$ and $2T_{1u}\pi$ states, respectively, are responsible for the high-energy and low-energy sets of excitation bands.

Based on the presented experimental results, the scheme of levels of Cu$^+$ and Cu$^{2+}$ ions in CsBr host is shown in Fig. 5.

![Fig. 5. Scheme of levels of Cu$^+$ and Cu$^{2+}$ ions in CsBr host and possible mechanism of excitation of their luminescence.](image)

Concluding, existence of the luminescence bands of different origin (intrinsinc radiative transition of Cu$^+$ ions, recombination luminescence of Cu$^{2+}$ ions and luminescence of excitons localized around Cu$^+$ and Cu$^{2+}$ ions) was found in CsBr:Cu and CsBr:CuBr$\_2$ crystals. This reflects the complicated character of formation of the luminescence centers in CsBr host due to copper doping, which can participate in the storage or TL processes in such phosphors. The energy scheme of Cu$^+$ and Cu$^{2+}$ ions in the CsBr host in the 3.7–10 eV range, and related with them low energy excitation, were clarified using the absorption and excitation spectra of luminescence of these ions under excitation by synchrotron radiation. Apart the intrinsic and charge-transfer transition related to the Cu$^+$ and Cu$^{2+}$ ions we confirm in this work the existence of excitons localized around these ions and determined their energy of creation to be equal to 6.06 eV and 6.09 eV at 10 K, respectively. The radiative decay of such excitons results in the luminescence in the band peaked at 3.08 eV and 3.385 eV, respectively. We also found that the energy of creation of excitons bound with the Cu$^+$ and Cu$^{2+}$ equals 5.83 eV and 5.99 eV at 300 K, respectively. Radiative annihilation of such type excitons results in the Cu$^+$ emission in the band peaked at 2.61 eV and 2.235 eV, and Cu$^{2+}$ emission in the bands peaked at 2.55 eV and 2.13 eV. The doublet character of these bands can be related to both — formation of the off-centre configuration of Cu$^+$ and Cu$^{2+}$ ions and creation of Cu-based dimer centers.
