We perform a likelihood analysis of the constraints from accelerator experiments and astrophysical observations on supersymmetric (SUSY) models with SU(5) boundary conditions on soft SUSY-breaking parameters at the GUT scale. The parameter space of the models studied has 7 parameters: a universal gaugino mass $m_{1/2}$, distinct masses for the scalar partners of matter fermions in five- and ten-dimensional representations of SU(5), m_5 and m_{10} , and for the $\mathbf{5}$ and $\bar{\mathbf{5}}$ Higgs representations m_{H_u} and m_{H_d} , a universal trilinear soft SUSY-breaking parameter A_0 , and the ratio of Higgs vevs $\tan \beta$. In addition to previous constraints from direct sparticle searches, low-energy and flavour observables, we incorporate constraints based on preliminary results from 13 TeV LHC searches for jets + \cancel{E}_T events and long-lived particles, as well as the latest PandaX-II and LUX searches for direct Dark Matter detection. In addition to previously-identified mechanisms for bringing the supersymmetric relic density into the range allowed by cosmology, we identify a novel $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation mechanism that appears in the supersymmetric SU(5) GUT model and discuss the role of $\tilde{\nu}_\tau$ coannihilation. We find complementarity between the prospects for direct Dark Matter detection and SUSY searches at the LHC.

1. Introduction

In the absence so far of any experimental indications of supersymmetry (SUSY) [1–5], nor any clear theoretical guidance how SUSY may be broken, the building of models and the exploration of phenomenological constraints on them [6–11] have adopted a range of assumptions. One point of view has been to consider the simple parametrization of soft SUSY breaking in which the gaugino and scalar masses, as well as the trilinear soft SUSY-breaking parameters, are all constrained to be universal at the SUSY GUT scale (the CMSSM [6, 7, 12–15]). An alternative point of view has been to discard all universality assumptions, and treat the soft SUSY-breaking parameters as all independent phenomenological quantities (the pMSSM [9, 16]), imposing diagonal mass matrices and the minimal flavour violation (MFV) criterion. Intermediate between these extremes, models with one or two non-universal soft SUSY-breaking contributions to Higgs masses (the NUHM1 [6, 7, 17–20] and NUHM2 [8, 18–22]) have also been considered.

It is interesting to explore also models that are less (over-)simplified than the CMSSM, but not as agnostic as the pMSSM, in that they incorporate a limited number of simplifying assumptions. GUTs motivate the assumption that the gaugino masses are universal, and constraints on flavour-changing neutral interactions suggest that the soft SUSY-breaking masses for scalars with identical quantum numbers are also universal. However, there is no compelling phenomenological reason why the soft SUSY-breaking masses for scalars with different quantum numbers should be universal.

Specific GUTs may also provide some guidance in this respect. For example, in an SO(10) GUT the scalar masses of all particles in a given generation belonging to a single **16** representation of SO(10) would be universal, as would those for the **5** and $\bar{\mathbf{5}}$ SU(5) Higgs representations that belong to a single **10** of SO(10) and break electroweak symmetry, as in the NUHM1. In contrast, the SU(5) framework is less restrictive, allowing different masses for scalars in $\bar{\mathbf{5}}$ and **10** representations [23], and also for the **5** and $\bar{\mathbf{5}}$ Higgs repre-

sentations. Thus it is a 1-parameter extension of the NUHM2. In this paper we explore the theoretical, phenomenological, experimental and cosmological constraints on this SU(5)-based SUSY GUT model.

This relaxation of universality is relevant for the evaluation of several different constraints from both the LHC and elsewhere. For example, the most powerful LHC constraints on the CMSSM, NUHM1 and NUHM2 are those from the classic \cancel{E}_T searches [1, 4]. These constrain principally the right-handed squarks, whose decays are dominated by the $\tilde{q}_R \rightarrow q \tilde{\chi}_1^0$ channel that maximizes the \cancel{E}_T signature. On the other hand, the decay chains of left-handed squarks are more complicated, typically involving the $\tilde{\chi}_1^\pm$, resulting in a dilution of the \cancel{E}_T signature and more importance for final states including leptons. In a SUSY SU(5) GUT, the left-handed squarks and the right-handed up-type squarks appear in **10** representations whereas the right-handed down-type squarks appear in $\bar{\mathbf{5}}$ representations, with independent soft SUSY-breaking masses. Hence the impacts of the LHC \cancel{E}_T and other constraints need to be re-evaluated.

The possible difference between the soft SUSY-breaking contributions to the masses of the squarks appearing in a **10** of SU(5), i.e., up-type squarks and left-handed down-type squarks, and those appearing in a $\bar{\mathbf{5}}$ of SU(5), i.e., right-handed down-type squarks, may also be relevant to the possibility of a compressed stop spectrum. Also, as we shall see, with $m_5 \neq m_{10}$ there is the possibility that $m_{\tilde{u}_R, \tilde{c}_R}$ are much smaller than the other squark masses, leading to another type of compressed spectrum.

In principle, the constraints from flavour observables may also act differently when $m_5 \neq m_{10}$. For example, the soft SUSY-breaking masses of the left- and right-handed charge +2/3 quarks are independent, and flavour observables such as $\text{BR}(b \rightarrow s\gamma)$ and $\text{BR}(B_s \rightarrow \mu^+\mu^-)$ depend on both of them, in general.

Another experimental constraint whose interpretation may be affected by the non-universality of scalar masses is $(g-2)_\mu$. *A priori*, a SUSY explanation of the discrepancy between the Standard Model (SM) prediction and the experimen-

tal measurement of $(g-2)_\mu$ requires relatively light smuons, either right- and/or left-handed, which are in $\mathbf{10}$ and $\bar{\mathbf{5}}$ representations, respectively. It is interesting to investigate to what extent the tension between a SUSY interpretation of $(g-2)_\mu$ and the LHC constraints on squarks that is present in more constrained SUSY models could be alleviated by the extra degree of freedom afforded by the $\bar{\mathbf{5}} - \mathbf{10}$ disconnect in SU(5).

Finally, we recall that in large parts of the regions of the CMSSM, NUHM1 and NUHM2 parameter spaces favoured at the 68% CL the relic $\tilde{\chi}_1^0$ density is brought into the range allowed by Planck [24] and other data via coannihilation with the stau and other sleptons [25, 26]. In an SU(5) GUT, the left- and right-handed sleptons are in different representations, $\bar{\mathbf{5}}$ and $\mathbf{10}$, respectively. Hence they have different masses, in general, providing more flexibility in the realization of coannihilation. Specifically, as mentioned above, the freedom to have $m_5 \neq m_{10}$ allows the possibility that the right-handed up- and charm-flavour squarks, \tilde{u}_R and \tilde{c}_R , are much lighter than the other squarks, opening up the novel possibility of $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation, as we discuss below.

Our analysis of the available experimental constraints largely follows those in our previous studies of other variants of the MSSM [6–11], the main new feature being that we incorporate the constraints based on the preliminary results from LHC searches for jets + \cancel{E}_T events with $\sim 13/\text{fb}$ of data at 13 TeV [5]. For this purpose, we recast available results for simplified models with the mass hierarchies $m_{\tilde{q}} \gg m_{\tilde{q}}$ and vice versa. We also include the preliminary constraints from LHC searches in 13-TeV data for the heavy MSSM Higgs bosons and long-lived charged particles, and incorporate in combination the recent PandaX [27] and LUX [28] data.

The SUSY SU(5) GUT model we study is set up in Section 2, and our implementations of constraints and analysis procedure are summarized in Section 3. Section 4 describes how we characterize different Dark Matter (DM) mechanisms, including the novel $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation mechanism, $\tilde{\nu}_\tau$ coannihilation and various hybrid possibilities. Section 5 contains our results in several model parameter planes, and Section 6 de-

scribes various one-dimensional likelihood functions including those for several sparticle masses, $(g-2)_\mu$ and various other observables. Higgs boson branching ratios (BRs) and are presented in Section 7, followed by a comparison of the SU(5) with the NUHM2 results in Section 8. The possibility of a long-lived $\tilde{\tau}_1$ is discussed in Section 9, and the prospects for direct DM detection are discussed in Section 10. Finally, Section 11 presents a summary and some conclusions.

2. Supersymmetric SU(5) GUT Model

We assume a universal, SU(5)-invariant gaugino mass parameter $m_{1/2}$, which is input at the GUT scale, as are the other SUSY-breaking parameters listed below.

We assume the conventional multiplet assignments of matter fields in the minimal superymmetric GUT:

$$(q_L, u_L^c, e_L^c)_i \in \mathbf{10}_i, \quad (\ell_L, d_L^c)_i \in \bar{\mathbf{5}}_i, \quad (1)$$

where the subscript $i = 1, 2, 3$ is a generation index. The only relevant Yukawa couplings are those of the third generation, particularly that of the t quark (and possibly the b quark and the τ lepton) that may play an important role in generating electroweak symmetry breaking. In our discussion of flavour constraints, we assume the MFV scenario in which generation mixing is described by the Cabibbo-Kobayashi-Maskawa (CKM) model. This is motivated by phenomenological constraints on low-energy flavour-changing neutral interactions, as is our assumption that the soft SUSY-breaking scalar masses for the different $\mathbf{10}_i$ and $\bar{\mathbf{5}}_i$ representations are universal in generation space, and are denoted by m_{10} and m_5 , respectively. In contrast to the CMSSM, NUHM1 and NUHM2, we allow $m_5 \neq m_{10}$. We assume a universal soft trilinear SUSY-breaking parameter A_0 .

We assume the existence of two Higgs doublets H_u and H_d in $\mathbf{5}$ and $\bar{\mathbf{5}}$ representations that break electroweak symmetry and give masses to the charge +2/3 and charge -1/3 and -1 matter fields, respectively. It is well known that this assumption gives a (reasonably) successful relation between the masses of the b quark and the τ lep-

ton [29], but not for the lighter charge $-1/3$ quarks and charged leptons. We assume that whatever physics resolves this issue is irrelevant for our analysis, as would be the case, for instance, if corrections to the naive $SU(5)$ mass relations were generated by higher-dimensional superpotential terms [30]. In the absence of any phenomenological constraints, we allow the soft SUSY-breaking contributions to the H_u and H_d masses, m_{H_u} and m_{H_d} , to be different from each other, as in the NUHM2, as well as from m_5 and m_{10} . As in the CMSSM, NUHM1 and NUHM2, we allow the ratio of Higgs vacuum expectation values, $\tan\beta$, to be a free parameter.

In addition to these electroweak Higgs representations, we require one or more Higgs representations to break the $SU(5)$ GUT symmetry. The minimal possibility is a single **24** representation Σ , but we do not commit ourselves to this minimal scenario. It is well known that this scenario has problems with rapid proton decay¹ and GUT threshold effects on gauge coupling unification. We assume that these issues are resolved by the appearance of additional fields at or around the GUT scale that are otherwise irrelevant for TeV-scale phenomenology. The effective low-energy Higgsino mixing coupling μ is a combination of an input bilinear $H_u H_d$ coupling and possible trilinear and higher-order couplings to GUT-scale Higgs multiplets such as $H_u \Sigma H_d$. We assume that these combine to yield $\mu = \mathcal{O}(1)$ TeV and positive, without entering into the possibility of some dynamical mechanism, and commenting below only briefly on the case $\mu < 0$.

3. Implementations of Constraints and Analysis Procedure

Our treatments in this paper of many of the relevant constraints follow very closely the implementations in our previous analyses of other supersymmetric models [6–10]. For the convenience of the reader, we summarise the constraints in Table 1. In the following subsections we review our implementations, highlighting new constraints and instances where we implement con-

straints differently from our previous work.

3.1. Electroweak and Flavour Constraints

We treat as Gaussian constraints all electroweak precision observables, all B -physics and K -physics observables except for $\text{BR}(B_{s,d} \rightarrow \mu^+ \mu^-)$. The χ^2 contribution from $\text{BR}(B_{s,d} \rightarrow \mu^+ \mu^-)$, combined here in the quantity $R_{\mu\mu}$ [7], is calculated using a combination of the CMS [31] and LHCb [32] results described in [33] with the more recent result from ATLAS [34]. The corresponding χ^2 contribution is labelled as “2D likelihood” in Table 1. We calculate the elements of the CKM matrix using only experimental observables that are not included in our set of flavour constraints.

We have updated our implementations of all the flavour constraints, and now use the current world average value of m_t [35]. These and all other constraints whose implementations have been changed are indicated by arrows and boldface in Table 1.

3.2. Higgs Constraints

We use the combination of ATLAS and CMS measurements of the mass of the Higgs boson: $M_h = 125.09 \pm 0.24$ GeV [44]. We employ the `FeynHiggs 2.11.2` code [42, 43] to evaluate the constraint this imposes on the parameter space, assuming a one- σ theoretical uncertainty of 1.5 GeV².

The χ^2 contributions of 77 Higgs search channels from the LHC and the Tevatron are evaluated using `HiggsSignals`, see [62], where a complete list of references can be found. The χ^2 contributions from the limits from searches for the heavy neutral MSSM Higgs bosons in the $H/A \rightarrow \tau^+ \tau^-$ channels are evaluated using the code `HiggsBounds` [60, 63], which incorporates the results of CMS searches [59, 60] with $\sim 25 \text{ fb}^{-1}$ of 8 TeV data. The contributions from the two possible production modes, $gg \rightarrow H/A$ and $b\bar{b} \rightarrow H/A$, are combined in a consistent manner, depending on the MSSM parameters. The results from `HiggsBounds` have been compared with the

¹We note that this problem becomes less severe for supersymmetry-breaking scales beyond a TeV [20].

²We use a modified version of `FeynHiggs 2.11.2` that includes two-loop QCD corrections in the evaluation of the $\overline{\text{DR}}$ running top mass and an improved evaluation of the top mass in the $\overline{\text{DR}}$ -on-shell conversion for the scalar tops.

published CMS analysis, and are in very good agreement [60]. The corresponding χ^2 contribution is labelled as “2D likelihood” in Table 1. For the corresponding constraint with 13 fb⁻¹ of 13 TeV data, we implement an approximate treatment of the χ^2 contribution using the preliminary result of ATLAS [61], as we describe in more detail below. Limits from other Higgs boson searches are not relevant for the investigation in this paper and are therefore not included.

3.3. LHC \cancel{E}_T constraints at 13 TeV

ATLAS and CMS have recently announced preliminary results from \cancel{E}_T searches with $\sim 13/\text{fb}$ of data at 13 TeV, using simplified models for gluino and squark pair production [3, 5]. These searches assume $m_{\tilde{g}} \ll m_{\tilde{q}}$ and $m_{\tilde{q}} \ll m_{\tilde{g}}$, respectively, and 100% BRs for the decays $\tilde{g} \rightarrow f\bar{f}\tilde{\chi}_1^0$ ($f = q, b, t$) and $\tilde{q} \rightarrow q\tilde{\chi}_1^0$, respectively, which maximize the possible corresponding \cancel{E}_T signatures. Neither of these assumptions is valid in the SUSY SU(5) GUT model: as we will see in more detail later, the $m_{\tilde{g}}$ and $m_{\tilde{q}}$ masses are quite similar in much of the favoured region of parameter space³, and in general other decay modes dilute the \cancel{E}_T signature, although larger-multiplicity final states may compensate through an increase in transverse energy H_T [64]. These other decay modes populate other search channels including leptons, which we do not consider in this paper as they were of limited importance in our previous analyses of the CMSSM, NUHM1 and NUHM2, having impact only for relatively large squark masses and small $m_{1/2}$.

Fig. 1 displays the ratios of the $\tilde{g}\tilde{g}$ cross section (left panel) and the $\tilde{q}\tilde{q} + \tilde{q}\tilde{\bar{q}}$ cross section (right panel) that we find in ranges of $m_{\tilde{q}}$ and $m_{\tilde{g}}$ that are representative of those favoured in our analysis before implementing the LHC 13-TeV \cancel{E}_T constraint, relative to the cross sections found in the simplified models with $m_{\tilde{g}} \ll m_{\tilde{q}}$ and $m_{\tilde{q}} \ll m_{\tilde{g}}$, respectively. We have used NLL-fast-3.1 [65] to obtain the cross section at NLO + NLL level. In both plots a large area

at higher squark masses is visible, as well as a thin strip at ~ 500 GeV. The latter corresponds to lighter \tilde{u}_R and \tilde{c}_R discussed below. We see that the $\tilde{g}\tilde{g}$ cross section (left panel) is generally *smaller* than in the corresponding simplified model by a factor > 2 due to the destructive interference between the s -channel gluon exchange diagram and the t -channel squark exchange diagram in $q\bar{q} \rightarrow \tilde{g}\tilde{g}$, thus weakening the LHC constraints as discussed below. On the other hand, the $\tilde{q}\tilde{q} + \tilde{q}\tilde{\bar{q}}$ cross section (right panel) is generally *a factor $\gtrsim 10$ larger* than in the simplified model, except in the $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation strip at small $m_{\tilde{u}_R}, m_{\tilde{c}_R}, m_{\tilde{\chi}_1^0} \sim 500$ GeV and $m_{1/2} \sim 2500$ GeV, to which we return later. The enhancement of the squark cross-section is due to the fact that in the squark-neutralino simplified model there is no production mode with total baryon number $B = 2/3$; $q\bar{q} \rightarrow \tilde{q}\tilde{\bar{q}}$, because gluinos are assumed to be absent. On the other hand, in our model $m_{\tilde{g}} \sim \min(m_{\tilde{q}})$, and $q\bar{q} \rightarrow \tilde{q}\tilde{\bar{q}}$ (with t -channel \tilde{g} exchange) becomes the dominant squark production mode in the large $m_{\tilde{q}}$ region, due to the valence quark-parton dominance in the proton in the large x regime.

Fig. 2 displays the CMS 95% confidence limits in the $(m_{\tilde{g}}, m_{\tilde{\chi}_1^0})$ plane from a hadronic jets plus \cancel{E}_T search [5] within a simplified model assuming that the decay mode $\tilde{g} \rightarrow q\bar{q}\tilde{\chi}_1^0$ occurs with 100% BR (solid black lines). These limits are compared with the best-fit points (green stars) and the regions in the fits that are preferred at $\Delta\chi^2 = 2.30$ and $\Delta\chi^2 = 5.99$ (red and blue contours, respectively). Here and in the following analogous parameter planes, we use the $\Delta\chi^2 = 2.30$ and $\Delta\chi^2 = 5.99$ contours as proxies for the boundaries of the 68% and 95% CL regions in the fit.

In addition, within the 95% CL region in Fig. 2 we have indicated the dominant ($> 50\%$) \tilde{g} decays found in our analysis. We note that many model points do not have any decay mode with BR $> 50\%$ within the 95% CL region and that, for those that do, the dominant decays are two-body $\tilde{g} \rightarrow \tilde{q}\tilde{\bar{q}}$ modes that were not considered in [5]. Because of this and the fact that the $\tilde{g}\tilde{g}$ cross section is always smaller than in the gluino simplified model by a factor > 2 (see the left

³An exception is provided by the \tilde{u}_R and \tilde{c}_R , which may be much lighter than the gluino and other squarks in some regions of parameter space. We will discuss this possibility in detail below.

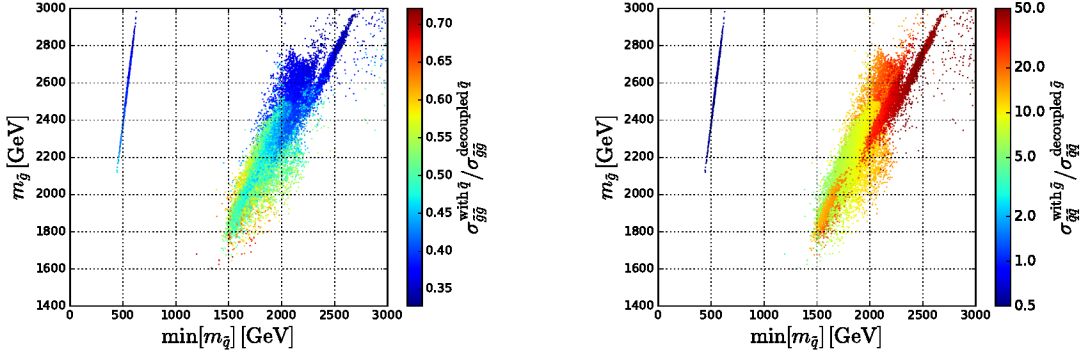

Figure 1. *Left panel:* the ratio of the $\tilde{g}\tilde{g}$ cross section that we find in the range of $m_{\tilde{q}}$ and $m_{\tilde{g}}$ favoured in our analysis before implementing the LHC 13-TeV \cancel{E}_T constraint, relative to the cross section found in the simplified model with $m_{\tilde{g}} \ll m_{\tilde{q}}$. *Right panel:* the corresponding ratio of the $\tilde{q}\tilde{q} + \tilde{q}\tilde{q}$ cross section, relative to the cross section for $\tilde{q}\tilde{q}$ found in the simplified model with $m_{\tilde{q}} \ll m_{\tilde{g}}$.

Figure 2. The solid lines show the CMS 95% CL exclusion in the $(m_{\tilde{g}}, m_{\tilde{\chi}_1^0})$ plane [5], assuming a simplified model with heavy squarks and 100% BR for $\tilde{g} \rightarrow q\tilde{q}\tilde{\chi}_1^0$. The left (right) panel shows the best-fit point (green star), 68 and 95% CL contours (red and blue lines, respectively) for $(m_{\tilde{g}}, m_{\tilde{\chi}_1^0})$ obtained without (with) the CMS 13-TeV constraint. The dominant ($> 50\%$) \tilde{g} decays into first- and second-generation quarks and squarks $\tilde{q}_{L,R}$ and third-generation quarks and squarks $\tilde{t}/\tilde{b}_{1,2}$ found in the SUSY SU(5) model are colour-coded as indicated.

panel of Fig. 1), the LHC 13-TeV \cancel{E}_T constraint from the gluino simplified model has only negligible impact. Our LHC 13-TeV \cancel{E}_T constraint on the gluino mass actually comes indirectly from the squark mass constraint estimated using the squark simplified model discussed below, since the the squark and gluino masses are related via renormalization group evolution in the SU(5) model. The left panel in Fig. 2 was obtained before implementing the LHC 13-TeV \cancel{E}_T 95% confidence limit on gluino and squark pair-production, while in the right panel this constraint is included. We note that the simplified model exclusion in this analysis extended to $m_{\tilde{g}} < 1900$ GeV, below the gluino mass at the pre-LHC 13 TeV best-fit point, and barely reaching the 68% CL contour (solid red line).

Fig. 3 contains an analogous set of planes for CMS \cancel{E}_T searches for squarks, where the CMS limit assuming a simplified model with heavy gluino and 100% BRs for $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ is displayed (black lines): the solid lines assume that all the squarks of the first two generations are degenerate, the dashed lines assume two degenerate squarks, and the dotted lines assume just one squark. The planes in the upper panels display $m_{\tilde{\chi}_1^0}$ and the masses of the first- and second-generation right-handed up-type squarks (here commonly denoted as \tilde{u}_R), while the planes in the lower panels are for the down-type squarks (here commonly denoted as \tilde{d}_R). The main decay modes of the \tilde{u}_R (upper) and the \tilde{d}_R (lower) are indicated over much of the preferred parameter space, and we note that the dominant (> 50%) decay modes of both right-handed up- and down-type squarks are indeed into the corresponding quark flavour + $\tilde{\chi}_1^0$ for nearly the whole 68% CL regions, as assumed in the squark simplified-model search. This is, however, not the case for the left-handed up- and down-type squarks (not shown), whose dominant decays are into $\tilde{\chi}_1^\pm$ and electroweak doublet partner quark flavours. Furthermore, within the displayed 95% CL regions there are also large areas where decays into gluinos, not considered in the simplified model, are dominant.

Because the $\tilde{q}_R \rightarrow q\tilde{\chi}_1^0$ decays are important, and also because the $\tilde{q}\tilde{q} + \tilde{q}\tilde{q}$ cross section in our

sample is much larger than that found at large $m_{\tilde{q}}$ for $\tilde{q}\tilde{q}$ in the simplified model with $m_{\tilde{q}} \ll m_{\tilde{g}}$, as seen in the right panel of Fig. 1, we have implemented a recast of this search in our global analysis⁴, and the comparison between the upper panels (without this contribution) and the lower panels (with this contribution) in Fig. 3 shows the importance of this constraint.

Our implementation of the LHC 13-TeV \cancel{E}_T constraint is based on [5]. In this analysis, the CMS Collaboration provides a map of the 95% CL cross-section upper limit as a function of $m_{\tilde{q}}$ and $m_{\tilde{\chi}_1^0}$ assuming $pp \rightarrow \tilde{q}\tilde{q}$ and 100% BR for $\tilde{q} \rightarrow q\tilde{\chi}_1^0$. This is indeed the dominant production and decay mode in most parts of the 68% CL regions of the considered model, as can be seen in Figs. 1 and 3. For each point we compare our calculation of $(\sigma_{\tilde{q}\tilde{q}} + \sigma_{\tilde{q}\tilde{q}}) \text{BR}_{\tilde{q} \rightarrow q\tilde{\chi}_1^0}^2$ with the CMS 95% CL upper limit on the cross section: $\sigma_{\text{UL}}(m_{\tilde{q}}, \tilde{\chi}_1^0)$. We model the χ^2 penalty as

$$\chi_{\tilde{q}}^2(\cancel{E}_T) = 5.99 \cdot \left[\frac{(\sigma_{\tilde{q}\tilde{q}} + \sigma_{\tilde{q}\tilde{q}}) \text{BR}_{\tilde{q} \rightarrow q\tilde{\chi}_1^0}^2}{\sigma_{\text{UL}}(m_{\tilde{q}}, \tilde{\chi}_1^0)} \right]^2, \quad (2)$$

so that the CMS 95% CL upper limit corresponds to $\chi^2(\cancel{E}_T) = 5.99$ and χ^2 scales as the square of the number of signal events, N_{sig} , which gives the right scaling.

The aforementioned CMS analysis [5] also looks at three simplified gluino models assuming 100% BR for $\tilde{g} \rightarrow f\tilde{f}\tilde{\chi}_1^0$ with $f = q, b, t$, respectively, and provides corresponding cross-section upper limit maps as a function of $m_{\tilde{g}}$ and $m_{\tilde{\chi}_1^0}$. We implement these constraints by defining $\chi_{\tilde{g} \rightarrow f\tilde{f}\tilde{\chi}_1^0}^2(\cancel{E}_T)$ by analogy with Eq. (2).

We also consider the $pp \rightarrow \tilde{q}\tilde{g}$ process, treating it as follows. This process is only relevant when $m_{\tilde{q}} \sim m_{\tilde{g}}$. In this regime, if $m_{\tilde{q}} > m_{\tilde{g}}$ ($m_{\tilde{g}} > m_{\tilde{q}}$), \tilde{q} (\tilde{g}) tends to decay into \tilde{g} (\tilde{q}), radiating soft jets. If these soft jets are ignored, we are left with the $\tilde{g}\tilde{g}$ ($\tilde{q}\tilde{q}$) system. In this approximation, the impact of $pp \rightarrow \tilde{q}\tilde{g}$ can therefore be estimated by adding an extra contribution $\sigma_{\tilde{q}\tilde{g}} \text{BR}_{\tilde{q} \rightarrow \tilde{q}\tilde{g}}$ ($\sigma_{\tilde{q}\tilde{g}} \text{BR}_{\tilde{g} \rightarrow \tilde{q}\tilde{q}}$) to $\sigma_{\tilde{g}\tilde{g}}$ ($\sigma_{\tilde{q}\tilde{q}} + \sigma_{\tilde{q}\tilde{q}}$). In general, SUSY searches are

⁴The $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation strip visible in the left panels of Fig. 3 at $m_{\tilde{u}_R} \simeq m_{\tilde{\chi}_1^0} \sim 500$ GeV is the subject of a later dedicated discussion.

Figure 3. The black lines show the CMS 95% CL exclusion in the $(m_{\tilde{q}}, m_{\tilde{\chi}_1^0})$ plane [5], assuming a simplified model with heavy gluinos and 100% BR for $\tilde{q} \rightarrow q\tilde{\chi}_1^0$: the solid lines assume that all the squarks of the first two generations are degenerate, the dashed lines assume two degenerate squarks, and the dotted lines assume just one squark. The left panels show the best-fit point (green star), 68 and 95% CL contours (red and blue lines, respectively) for $m_{\tilde{\chi}_1^0}$ and the masses of the first- and second-generation right-handed up-type squarks \tilde{u}_R (upper panel) and the down-type squarks \tilde{d}_R (lower panel). In both cases, the left panels were obtained without the CMS 13-TeV constraint, and the right panels include it. The dominant (> 50%) \tilde{q} decays found in the SUSY SU(5) model are colour-coded as indicated.

designed to look for high p_T objects, and one loses a small amount of sensitivity by ignoring soft jets. We therefore believe that our implementation of the $pp \rightarrow \tilde{q}\tilde{g}$ process is conservative.

Finally, we estimate the total χ^2 penalty from the LHC 13-TeV \cancel{E}_T constraint to be $\chi^2(\cancel{E}_T) = \chi_q^2(\cancel{E}_T) + \sum_{f=q,b,t} \chi_{\tilde{g} \rightarrow f\tilde{\chi}_1^0}^2(\cancel{E}_T)$.

3.4. Constraints on long-lived charged particles

We also include in our analysis LHC constraints from searches for heavy long-lived charged particles (HLCP) that are, in general, relevant to coannihilation regions where the mass difference between the lightest SUSY particle (LSP) and the next-to-lightest SUSY particle (NLSP) may be small and the NLSP may therefore be long-lived. As we discuss below, important roles are played in our analysis by $\tilde{\tau}_1$, $\tilde{\chi}_1^\pm$ and \tilde{u}_R/\tilde{c}_R coannihilation, but only in the $\tilde{\tau}_1$ case is the NLSP - LSP mass difference small enough to offer the possibility of a long-lived charged particle. We implement in our global analysis the preliminary CMS 13-TeV result [57] using tracking and time-of-flight measurements, based on the recipe and the efficiency map as a function of the pseudorapidity and velocity of the HLCP given in [58]. We use `Pythia 8` [66] and `Atom` [67] to generate and analyse the events, and assume that the efficiencies for detecting slow-moving $\tilde{\tau}_1$ s are similar at 8 and 13 TeV.⁵ The efficiency contains a lifetime-dependent factor $\propto \exp(-dm/p\tau)$, where d is a distance $d \simeq 10$ m that depends on the pseudorapidity, and m , p and τ are the mass, momentum and lifetime of the long-lived particle. This factor drops rapidly for particles with lifetimes $\lesssim 10$ ps, corresponding to $m_{\tilde{\tau}_1} - m_{\tilde{\chi}_1^0} \gtrsim 1.6$ GeV.

3.5. Constraints on heavy neutral Higgs bosons from Run II

Concerning the production of heavy neutral Higgs bosons, in addition to the 8 TeV constraints on $H/A \rightarrow \tau^+\tau^-$ provided by `HiggsBounds`, we also take into account the preliminary exclusion limits obtained by ATLAS from searches for generic spin-0 bosons ϕ in the $\tau\tau$ final state with an integrated luminosity of 13.3 fb^{-1} at 13 TeV that were presented at the ICHEP 2016 conference and described in [61]. Upper bounds on $\sigma \times \text{BR}(\phi \rightarrow \tau\tau)$ are reported for each M_ϕ separately for the gluon fusion production channel and for production in association with a $b\bar{b}$ pair assuming there is no contamination between the modes, assuming a single resonance. We compute

⁵A similar recasting method was used in [68]. See also [69] for another approach using simplified model topologies.

the cross sections and the BRs in the MSSM using `FeynHiggs`, adding the contributions for $\phi = H$ and $\phi = A$, using the average of the two masses, which are degenerate within the experimental resolution. This result is compared with the upper limit from the corresponding channel neglecting contamination. This approach leads to a conservative limit since we underestimate the signal yield in each channel by neglecting the contamination (the events from the other production mode). As in Eq. (2), the χ^2 penalties are modelled as

$$\chi^2(Y_i) = 4 \cdot \left(\frac{\sigma_{X_i} \cdot \text{BR}_{\tau^+\tau^-}}{\sigma_{Y_i}^{\text{UL}}(M_A)} \right)^2, \quad (3)$$

where $X_i = (gg \rightarrow H/A, pp \rightarrow b\bar{b}H/A)$ is the production mode, $Y_i = (ggF, b\bar{b}\phi)$ is the corresponding search channel and $\sigma^{\text{UL}}(M_A)$ is the 95% CL upper limit evaluated at $M_A (\approx M_H)$ by ATLAS [61]. Finally we take the stronger χ^2 rather than combining them in order to be on the conservative side: $\chi^2(H/A \rightarrow \tau^+\tau^-) = \max(\chi^2(ggF), \chi^2(b\bar{b}\phi))$.

3.6. Other constraints

The most important other constraint update is that on spin-independent DM scattering. We incorporate in our global fit the recent result published by the PandaX-II experiment [27], which we combine with the new result from the LUX Collaboration [28], as discussed in more detail in Section 8.

For the electroweak observables we use `FeynWZ` [39], and for the flavour constraints we use `SuFla` [50]. For the Higgs observables, we use `FeynHiggs 2.11.2` [42, 43] (including the updates discussed in Sect. 3.2), `HiggsBounds 4.3.1` [63] and `HiggsSignals 1.4.0` [62]. We calculate the sparticle spectrum using `SoftSusy 3.10.10` [70] and sparticle decays using `SDECAY 1.3b` [71] and `StauDecay 0.1` [26]. The DM density and scattering rate are calculated using `micrOMEGAs 3.2` [55] and `SSARD` [56], respectively. Finally, we use `SLHALib 2.2` [72] to interface the different codes.

3.7. Sampling procedure

As discussed in the previous Section, the SUSY SU(5) GUT model we study has 7 parameters:

$m_{1/2}$, m_5 , m_{10} , m_{H_u} , m_{H_d} , A_0 and $\tan\beta$. The ranges of these parameters that we scan in our analysis are listed in Table 2. The quoted negative values actually correspond to negative values of m_5^2 , m_{10}^2 , $m_{H_u}^2$ and $m_{H_d}^2$: for convenience, we use the notation $\text{sign}(m^2) \times \sqrt{|m^2|} \rightarrow m$. The negative values of m_5 and m_{10} that are included in the scans may be compatible with early-Universe cosmology [73], and yield acceptable tachyon-free spectra. In the portions of the scans with negative values of m_{H_u} and m_{H_d} , although the effect of the top quark Yukawa coupling in the renormalization group equations is important, it may not be the dominant mechanism for generating electroweak symmetry breaking.

We sample this parameter space using `MultiNest v2.18` [74], dividing the 7-dimensional parameter space into 108 boxes, as also described in Table 2. For each box, we choose a prior such that 80% of the sample has a flat distribution within the nominal range, while 20% of the sample is in normally-distributed tails outside the box. Our resultant total sample overlaps smoothly between boxes, avoiding any spurious features at the box boundaries. The total number of points in our sample is $\sim 125 \times 10^6$, of which $\sim 8 \times 10^6$ have $\Delta\chi^2 < 10$.

4. Dark Matter Mechanisms

The relic density of the LSP, assumed here to be the lightest neutralino, $\tilde{\chi}_1^0$, which is stable in supersymmetric SU(5) because of R -parity, may be brought into the narrow range allowed by the Planck satellite and other measurements [24] via a combination of different mechanisms. It was emphasized previously [10] in studies of the CMSSM, NUHM1 and NUHM2 that simple annihilations of pairs of LSPs into conventional particles would not have been sufficient to bring the relic $\tilde{\chi}_1^0$ density down into the Planck range for values of $m_{\tilde{\chi}_1^0}$ compatible with the LHC search limits and other constraints on these models. Instead, there has to be some extra mechanism for suppressing the LSP density. Examples include enhanced, rapid annihilation through direct-channel resonances such as $Z, h, H/A$. Another possibility is coannihilation with some other, almost-degenerate spar-

ticle species: candidates for the coannihilating species identified in previous studies include the $\tilde{\tau}_1, \tilde{\mu}, \tilde{e}, \tilde{\nu}, \tilde{t}_1$ and $\tilde{\chi}_1^\pm$.

We introduced in [10] measures on the sparticle mass parameters that quantify the mass degeneracies relevant to the above-mentioned coannihilation and rapid annihilation processes, of which the following are relevant to our analysis of the SUSY SU(5) GUT model ⁶:

$$\begin{aligned} \tilde{\tau}_1 \text{ coann. (pink)} : & \quad \left(\frac{m_{\tilde{\tau}_1} - 1}{m_{\tilde{\chi}_1^0}} \right) < 0.15, \\ \tilde{\chi}_1^\pm \text{ coann. (green)} : & \quad \left(\frac{m_{\tilde{\chi}_1^\pm} - 1}{m_{\tilde{\chi}_1^0}} \right) < 0.1, \\ A/H \text{ funnel (pale blue)} : & \quad \left| \frac{M_A}{m_{\tilde{\chi}_1^0}} - 2 \right| < 0.4. \quad (4) \end{aligned}$$

We also indicate above the colour codes used in subsequent figures to identify regions where each of these degeneracy conditions applies. We have verified in a previous study [10] that CMSSM, NUHM1 and NUHM2 points that satisfy the DM density constraint fulfill one or more of the mass-degeneracy conditions, and that they identify correctly the mechanisms that yield the largest fractions of final states, which are usually $\gtrsim 50\%$ [8, 75].

In much of the region satisfying the $\tilde{\tau}_1$ degeneracy criterion above, the $\tilde{\nu}_\tau$ has a similar mass, and can contribute to coannihilation [22]. We highlight the parts of the sample where sneutrino coannihilation is important by introducing a shading for regions where the $\tilde{\nu}_\tau$ is the next-to-lightest sparticle (NLSP), and obeys the degeneracy condition

$$\tilde{\nu}_\tau^{\text{NLSP}} \text{ coann. (orange)} : \left(\frac{m_{\tilde{\nu}_\tau} - 1}{m_{\tilde{\chi}_1^0}} \right) < 0.1. \quad (5)$$

We discuss later the importance of this supplementary DM mechanism.

As we discuss in this paper, a novel possibility in the SU(5) SUSY GUT is coannihilation with right-handed up-type squarks, \tilde{u}_R and \tilde{c}_R , which

⁶We note that the focus-point mechanism does not play a role in the SU(5) model.

Parameter	Range	Number of segments
$m_{1/2}$	(0 , 4)	2
m_5	(- 2.6 , 8)	2
m_{10}	(- 1.3 , 4)	3
m_{H_u}	(-7 , 7)	3
m_{H_d}	(-7 , 7)	3
A_0	(-8 , 8)	1
$\tan \beta$	(2 , 68)	1
Total number of boxes		108

Table 2

Ranges of the SUSY SU(5) GUT parameters sampled, together with the numbers of segments into which each range was divided, and the corresponding total number of sample boxes. The mass parameters are expressed in TeV units.

may be much lighter than the other squarks in this model, as a consequence of the freedom to have $m_5 \neq m_{10}$. We quantify the relevant mass degeneracy criterion by

$$\tilde{u}_R/\tilde{c}_R \text{ coann. (yellow)} : \left(\frac{m_{\tilde{u}_R/\tilde{c}_R} - 1}{m_{\tilde{\chi}_1^0}} \right) < 0.2. \quad (6)$$

As we shall see in the subsequent figures, this novel degeneracy condition can play an important role when $m_5 \gg m_{10}$. The existence of this new coannihilation region was verified using SSARD [56].

We also distinguish in this analysis ‘hybrid’ regions where the $\tilde{\tau}_1$ coannihilation and H/A funnel mechanisms may be relevant simultaneously:

$$\tilde{\tau}_1 \text{ coann.} + H/A \text{ funnel} : \text{ (purple)}, \quad (7)$$

also with the indicated colour code.

5. Results

5.1. Parameter Planes

We display in Fig. 4 features of the global χ^2 function for the SUSY SU(5) GUT model in the $(m_5, m_{1/2})$ plane (left panel) and the $(m_{10}, m_{1/2})$ plane (right panel), profiled over the other model parameters. Here and in subsequent parameter planes, the best-fit point is shown as a green star, the 68% CL regions are surrounded by red contours, and the 95% CL regions are surrounded by

blue contours (as mentioned above, we use the $\Delta\chi^2 = 2.30$ and $\Delta\chi^2 = 5.99$ contours as proxies for the boundaries of the 68% and 95% CL regions in the fit). The regions inside the 95% CL contours are shaded according to the dominant DM mechanisms discussed in the previous Section, see the criteria (4, 6, 7). In the (relatively limited) unshaded regions there is no single dominant DM mechanism.

As we see in Fig. 4, the best-fit point is at relatively small values of m_5, m_{10} and $m_{1/2}$, close to the lower limit on $m_{1/2}$, whereas the 68% CL region extends to much larger values of m_5, m_{10} and $m_{1/2}$. The values of the model parameters at the best-fit point are listed in Table 3⁷. The upper row of numbers are the results from the current fit including the latest LHC 13-TeV and PandaX-II/LUX constraints, and the numbers in parentheses in the bottom row were obtained using instead the previous LHC 8-TeV and XENON100 constraints. The most significant effect of the new LHC data has been to increase the best-fit value of $m_{1/2}$ by ~ 300 GeV: the changes in the other fit parameters are not significant, in view of the uncertainties. As we discuss in more detail later, the favoured fit regions are driven towards the \cancel{E}_T boundary by the $(g-2)_\mu$ constraint. Away from this boundary, the global χ^2 function

⁷The SLHA files for the best-fit point and other supplementary material can be found in [11].

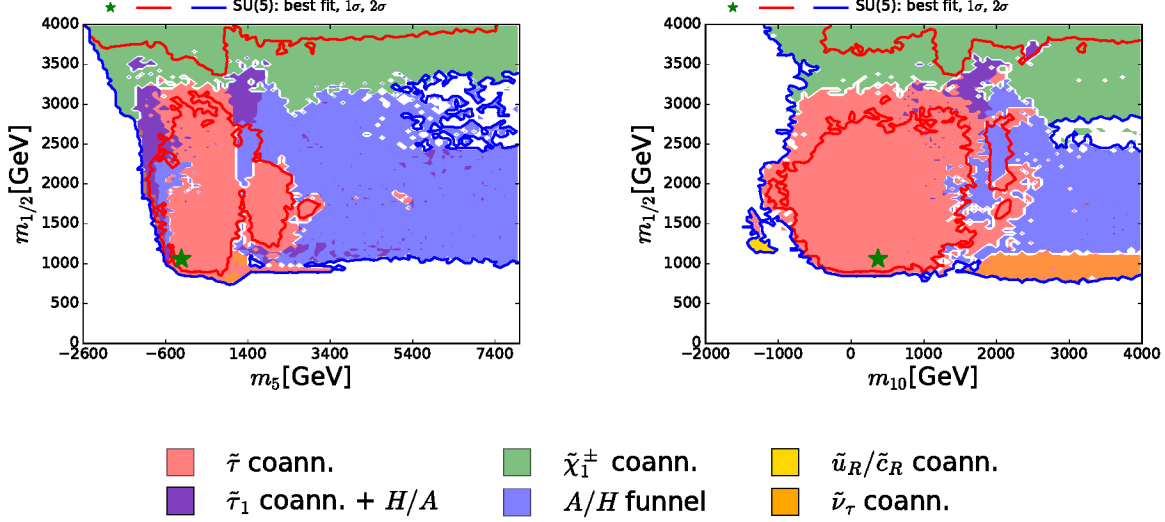

Figure 4. The $(m_5, m_{1/2})$ plane (left panel) and the $(m_{10}, m_{1/2})$ plane (right panel) in the SUSY SU(5) GUT model. The best-fit point is shown as a green star, the red contour surrounds the 68% CL region, and the blue contour surrounds the 95% CL region. The coloured shadings represent the dominant DM mechanisms, as indicated in the lower panel and described in the text.

is quite flat.

The best-fit point and much of the 68% CL region lie within the pink shaded region where $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation is the dominant DM mechanism. At larger values of m_5 and m_{10} we encounter a blue shaded region where rapid annihilation via direct-channel H/A poles is dominant. We also see darker shaded hybrid regions where $\tilde{\tau}_1$ and/or $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ coannihilation and H/A annihilation are important simultaneously. At larger values of $m_{1/2} \gtrsim 3000$ GeV, in the green shaded regions, the dominant DM mechanism is $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ coannihilation. There is also a band in the $(m_{10}, m_{1/2})$ plane with $m_{10} \gtrsim 1500$ GeV and $m_{1/2} \sim 1000$ GeV, allowed at the 95% CL, where $\tilde{\nu}_\tau^{\text{NLSP}}$ coannihilation is important.

We also note the appearance within the 95% CL region at $m_{1/2} \sim 1000$ GeV, and $m_{10} \sim -1000$ GeV of the novel $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation region (shaded yellow). To understand the origin of this novelty, consider the one-loop renormalization-group equations for the states in the $\mathbf{10}$ representations of SU(5), namely

$(q_L, u_L^c, e_L^c)_i$, above the highest MSSM particle mass (all masses are understood to be scalar fermion masses, and we suppress subscripts L):

$$16\pi^2 \frac{\partial m_{q_i}^2}{\partial t} = \delta_{i3}(X_t + X_b) - \frac{32}{3}g_3^2|M_3|^2 - 6g_2^2|M_2|^2 - \frac{2}{15}g_1^2|M_1|^2 + \frac{1}{5}g_1^2S, \quad (8)$$

$$16\pi^2 \frac{\partial m_{u_i^c}^2}{\partial t} = 2\delta_{i3}X_t - \frac{32}{3}g_3^2|M_3|^2 - \frac{32}{15}g_1^2|M_1|^2 - \frac{4}{5}g_1^2S, \quad (9)$$

$$16\pi^2 \frac{\partial m_{e_i^c}^2}{\partial t} = 2\delta_{i3}X_\tau - \frac{24}{5}g_1^2|M_1|^2 + \frac{6}{5}g_1^2S \quad (10)$$

where $t \equiv \ln(Q/Q_0)$ with Q the renormalization scale and Q_0 some reference scale,

$$X_t \equiv 2|y_t|^2(m_{H_u}^2 + m_{q_3}^2 + m_{t^c}^2) + 2|A_t|^2, \quad (11)$$

$$X_b \equiv 2|y_b|^2(m_{H_d}^2 + m_{q_3}^2 + m_{b^c}^2) + 2|A_b|^2, \quad (12)$$

$$X_\tau \equiv 2|y_\tau|^2(m_{H_d}^2 + m_{l_3}^2 + m_{\tau^c}^2) + 2|A_\tau|^2, \quad (13)$$

$m_{1/2}$	m_5	m_{10}	m_{H_u}	m_{H_d}	A_0	$\tan\beta$
1050	-220	380	-5210	-4870	-5680	12
(890)	(-80)	(310)	(-4080)	(-4420)	(5020)	(11)

Table 3

Parameters of the best-fit point in the SUSY SU(5) GUT model, with mass parameters given in GeV units. The numbers in parentheses in the bottom row are for a fit that does not include the LHC 13-GeV constraints and the recent PandaX-II and LUX constraints on DM scattering. Note that we use the same convention for the sign of A_0 as in [6–10], which is opposite to the convention used in, e.g., SoftSUSY, and that we use the notation $\text{sign}(m^2) \times \sqrt{|m^2|} \rightarrow m$ for m_5, m_{10}, m_{H_u} and m_{H_d} .

and

$$S \equiv (m_{H_u}^2 - m_{H_d}^2) + \text{Tr}(m_q^2 - m_l^2 - 2m_{u^c}^2 + m_{d^c}^2 + m_{e^c}^2), \quad (14)$$

where the trace in S sums over the generations. The $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation mechanism becomes important in a region of the SUSY SU(5) GUT parameter space where m_5^2 is very large and positive, m_{10}^2 is small and negative, $m_{H_u}^2$ is very large and negative, and $m_{H_d}^2$ is very large and positive. In this region, therefore, X_t is very large and negative, X_b and X_τ are suppressed because of small Yukawa couplings ($\tan\beta$ is not large in this region), and S is also very large and negative, since $m_{H_u}^2 - m_{H_d}^2$ is large and negative and $\text{Tr}(m_q^2 - m_l^2 - 2m_{u^c}^2 + m_{d^c}^2 + m_{e^c}^2)$ vanishes at the GUT scale. Inspection shows that the X_t terms in (8) and (9) drive the stop and sbottom masses upwards, and the S terms in (8) and (10) drive the left-handed squark and right-handed selectron masses upwards. On the other hand, the S term in (9) drives the right-handed squark masses downwards. Since there are no counteracting X terms for the \tilde{u}_R and \tilde{c}_R , these have lower masses than the other sfermions, opening the way to a $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation region.

As discussed in more detail later, we used the Atom [67] simulation code for a dedicated verification that points in this region escape all the relevant LHC constraints. These points avoid exclusion by the LHC constraints through a combination of a strong mass degeneracy, $m_{\tilde{u}_R/\tilde{c}_R} - m_{\tilde{\chi}_1^0} \lesssim 50$ GeV, leading to strong suppression of the standard \cancel{E}_T signature, and the reduction of the production rate compared to the simplified model that assumes mass degeneracy of all 8

light flavour squarks (see Fig. 1). These effects are clearly visible in Fig. 18 of [2].

Fig. 5 displays the corresponding information in the (m_5, m_{10}) plane of the SUSY SU(5) GUT model. As already reported in Table 3, here we see directly that the best-fit point has very small (and slightly negative) m_5 , and that m_{10} is somewhat larger, exploiting the possibility that $m_5 \neq m_{10}$ that is offered in this model. We also see again that the 68% CL region extends to values of m_5 and m_{10} beyond the $\tilde{\tau}_1$ coannihilation region. The novel $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation region is clearly visible as a band where $m_5 \gtrsim 2000$ GeV and $m_{10} \lesssim -1000$ GeV. We also note that in most of the rest of this plane $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ coannihilation is dominant, with only scattered regions where rapid H/A annihilation is important, even in combination with $\tilde{\tau}_1$ coannihilation.

Projections of our results in the $(\tan\beta, m_{1/2})$, $(\tan\beta, m_5)$ and $(\tan\beta, m_{10})$ planes are shown in Fig. 6. We see that values of $\tan\beta \gtrsim 4$ are allowed at the 95% CL, that the range $\tan\beta \in (8, 57)$ is favoured at the 68% CL, and that there is no phenomenological upper limit on $\tan\beta$ at the 95% CL⁸. The best-fit point has $\tan\beta = 13$, as also reported in Table 3.

The pink $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation region is very prominent in the $(\tan\beta, m_{1/2})$ projection shown in the upper panel of Fig. 6, as is the blue rapid H/A annihilation region and the purple $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation + H/A funnel hybrid region at large $\tan\beta$ and $m_{1/2}$. As previously, the $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ coannihilation region appears when $m_{1/2} \gtrsim 3000$ GeV, and this may hybridize with

⁸The RGE evolution of the Yukawa couplings blows up for $\tan\beta \gtrsim 60$.

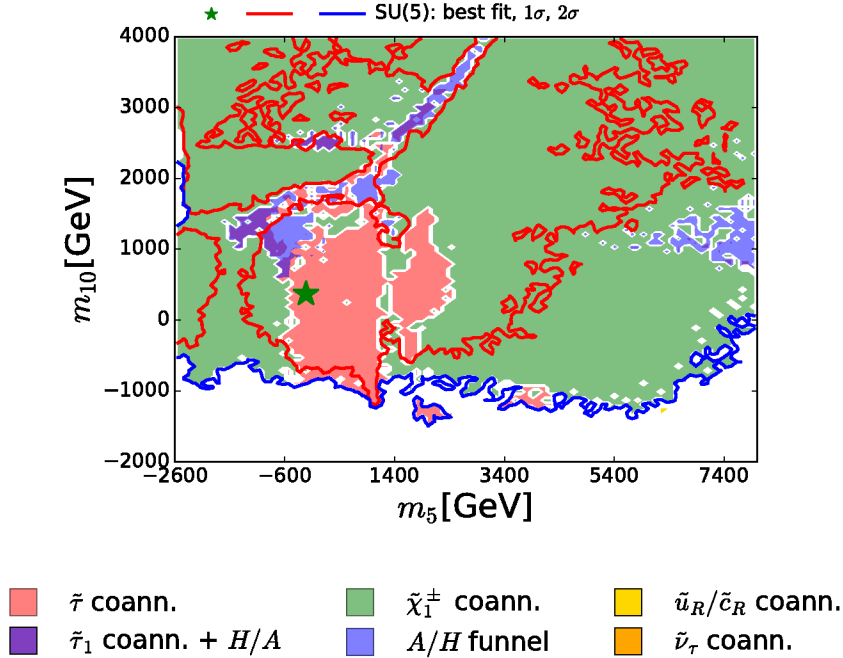

Figure 5. The (m_5, m_{10}) plane in the SUSY SU(5) GUT model. The line colours and shadings are the same as in Fig. 4.

$\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation and/or the H/A funnel, as seen in the mid and dark blue regions at $\tan\beta \sim 20$ and $m_{1/2} \in (1500, 2500)$ GeV. While the H/A funnel appears in the CMSSM only when $\tan\beta \gtrsim 45$ for $\mu > 0$ [12], in the SU(5) SUSY GUT model, it is found at significantly lower $\tan\beta$, due to the separation of m_{H_u} and m_{H_d} from m_5 and m_{10} , effectively making m_A (and μ) free parameters as in the NUHM2. There is also a region in the $(\tan\beta, m_{1/2})$ plane with $\tan\beta \lesssim 10$ and $m_{1/2} \sim 1000$ GeV where $\tilde{\nu}_\tau^{\text{NLSP}}$ coannihilation is important.

The $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation region and the purple $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation + H/A funnel hybrid region are prominent for $|m_5| \lesssim 3000$ GeV in the $(\tan\beta, m_5)$ and $(\tan\beta, m_{10})$ planes shown in the lower part of Fig. 6, with $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ coannihilation dominant at smaller values of $\tan\beta$, in particular. The $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation region is prominent for $\tan\beta \in (8, 20)$ and $m_{10} \sim -1200$ GeV

in the $(\tan\beta, m_{10})$ plane shown in the lower right panel of Fig. 6.

We display in Fig. 7 projections of our results for M_h versus $m_{1/2}$ (upper left), $\tan\beta$ (upper right), m_5 (lower left) and m_{10} (lower right). The predicted values of M_h are well centred within the expected **FeynHiggs** uncertainty range around the value measured at the LHC, $M_h = 125.09 \pm 0.24$ GeV [44]. Moreover, most of the Dark Matter mechanisms do not exhibit any preference for values of M_h above or below the nominal central value. Thus, there is no apparent tension between this LHC measurement and the other constraints on the SUSY SU(5) GUT model.

As is well known, the calculation of M_h in the MSSM is particularly sensitive to the value of the trilinear soft SUSY-breaking parameter A_0 as well as the stop squark masses. The latter depend in the SUSY SU(5) GUT model on m_{10} and $m_{1/2}$,

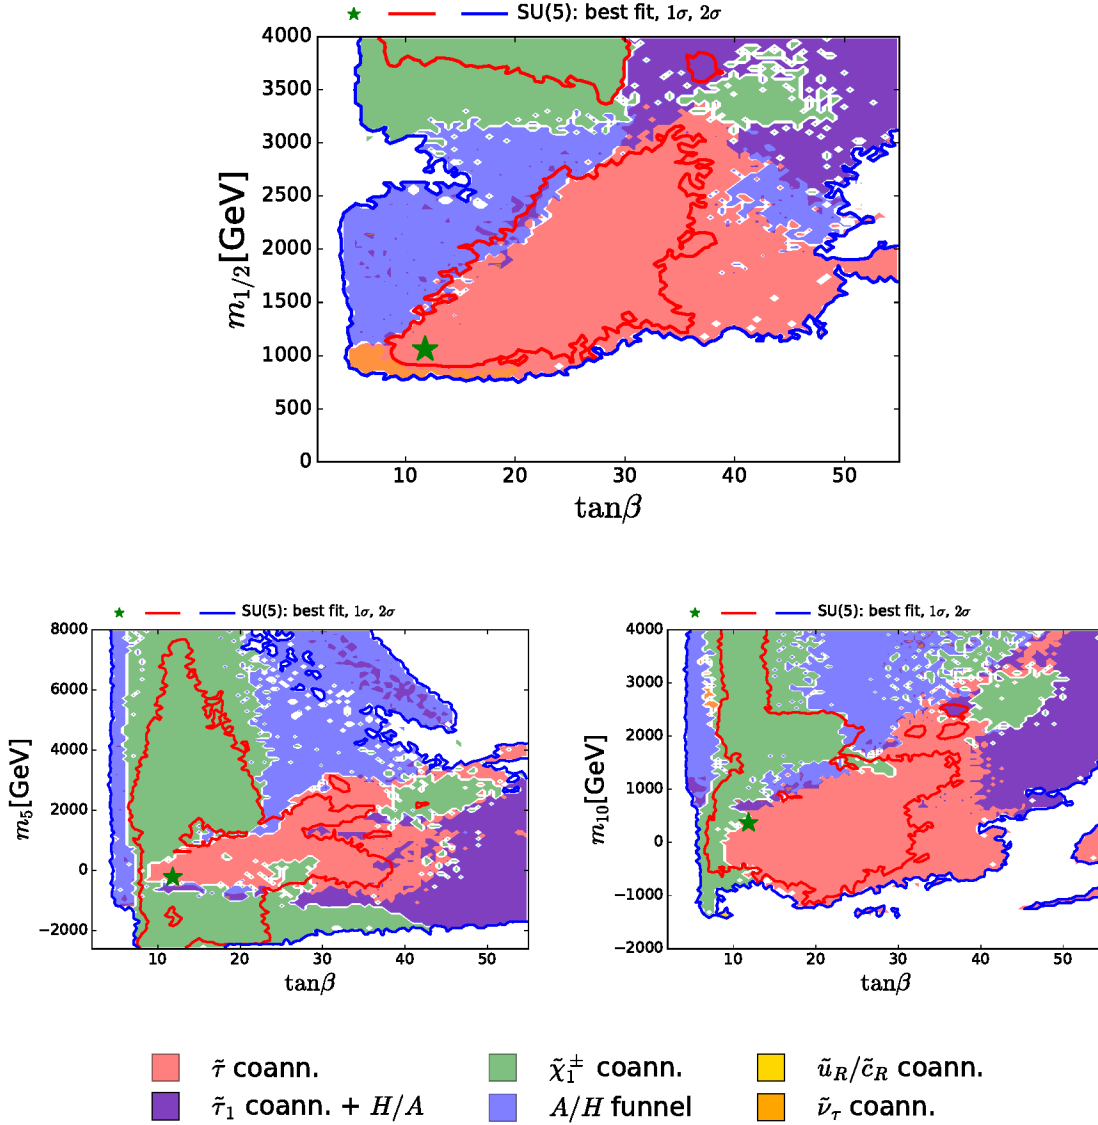

Figure 6. The $(\tan\beta, m_{1/2})$ plane (upper panel), the $(\tan\beta, m_5)$ plane (lower left panel) and the $(\tan\beta, m_{10})$ plane (lower right panel) in the SUSY SU(5) GUT model. The line colours and shadings are the same as in Fig. 4.

but are insensitive to m_5 .

The (m_{H_u}, m_{H_d}) plane is shown in Fig. 8. We see that the best-fit point lies in the quadrant where both m_{H_u} and m_{H_d} are negative, and that the 68% CL region extends also to the quadrant

where m_{H_d} is negative and m_{H_u} is positive, as does the $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation region. On the other hand, the $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ coannihilation region lies in the upper quadrants where $m_{H_d} > 0$. There is also an intermediate ‘hybrid’ region, much of

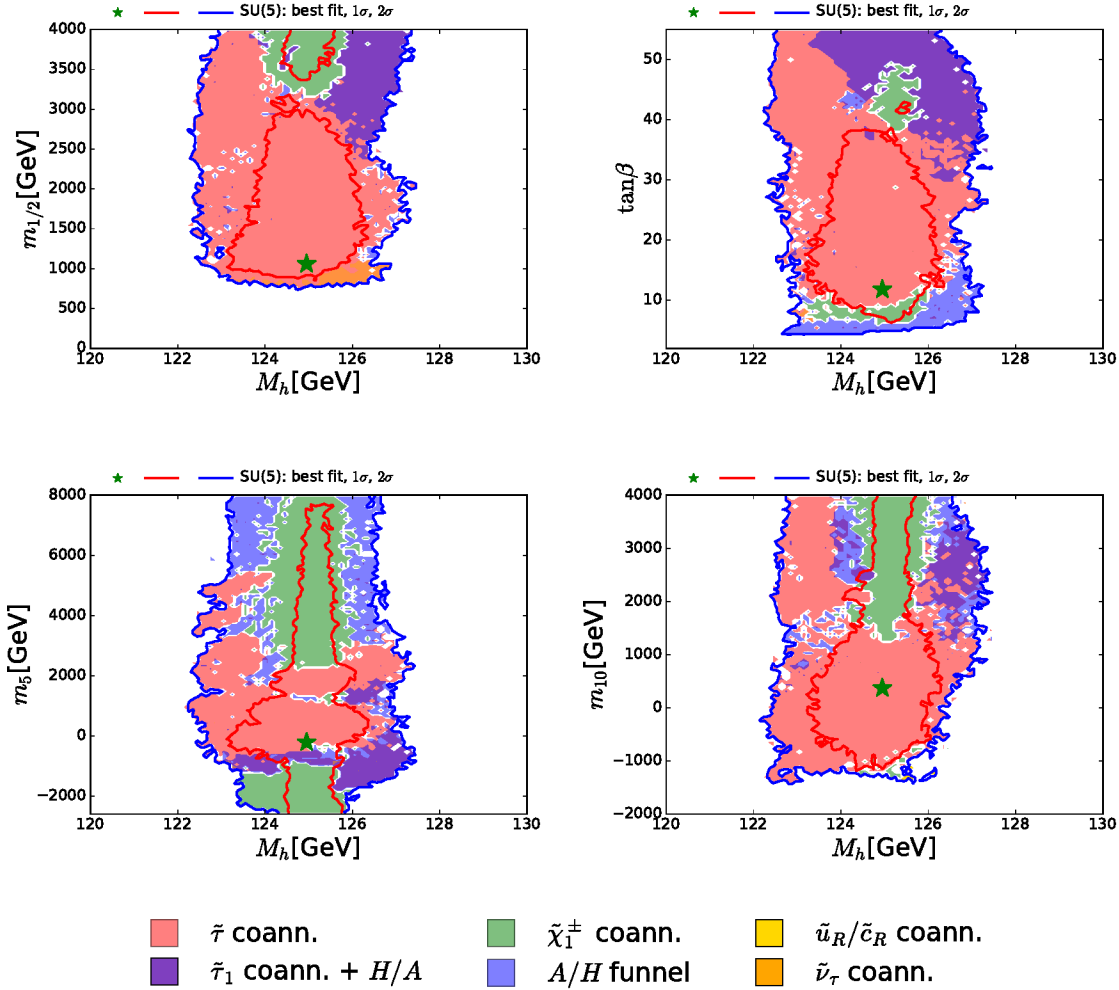

Figure 7. The $(M_h, m_{1/2})$ plane (upper left panel), the $(\tan \beta, M_h)$ plane (upper right panel), the (M_h, m_5) plane (lower left panel) and the (M_h, m_{10}) plane (lower right panel) in the SUSY SU(5) GUT model. The line colours and shadings are the same as in Fig. 4.

which is also allowed at the 68% CL. There is also a region with $M_{H_u} \sim 4000$ GeV, $M_{H_d} \sim -3000$ GeV where $\tilde{\nu}_\tau^{\text{NLSP}}$ coannihilation is important.

Fig. 9 displays the $(M_A, \tan \beta)$ plane in the supersymmetric SU(5) GUT model. We see that $M_A \gtrsim 800(1000)$ GeV at the 95 (68) % CL, which is largely due to the interplay of the indirect constraints on $(M_A, \tan \beta)$ rather than the

direct constraints from the LHC heavy MSSM Higgs searches. Even for large $\tan \beta$, where these constraints impose the strongest lower limit on M_A , it is much weaker than our global limit, which is $M_A \gtrsim 2800(> 4000)$ GeV at the 95 (68) % CL. The best-fit point in the global fit has $(M_A, \tan \beta) \simeq (1600 \text{ GeV}, 13)$: this is considerably beyond the present and projected LHC reach, though poorly determined.

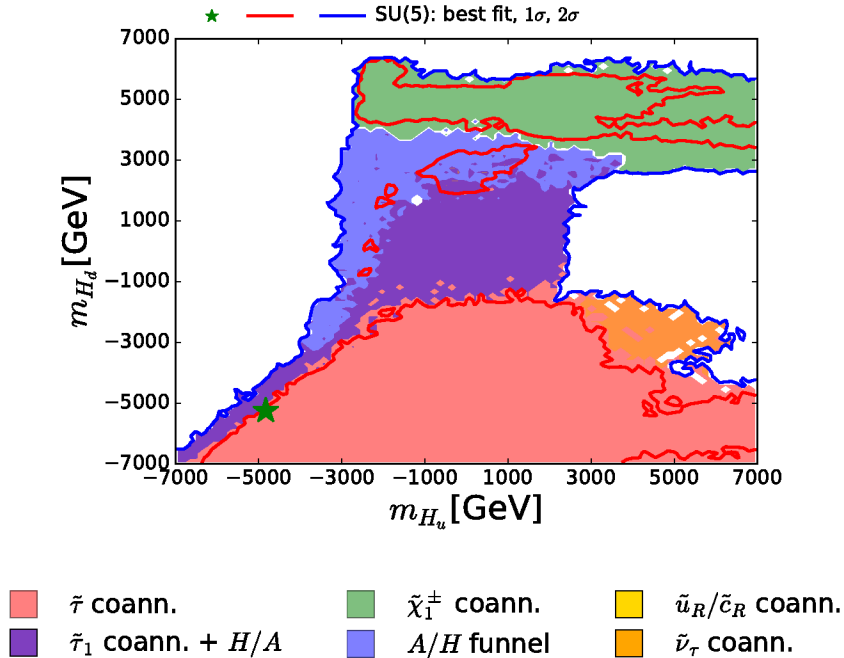

Figure 8. The (m_{H_u}, m_{H_d}) plane in the SUSY SU(5) GUT model. The line colours and shadings are the same as in Fig. 4.

6. One-Dimensional Likelihood Functions

We now discuss the one-dimensional $\Delta\chi^2$ functions for various observable quantities.

Fig. 10 displays those for $m_{\tilde{g}}$ (top left), $m_{\tilde{q}_L}$ (top right), $m_{\tilde{d}_R}$ (centre left), $m_{\tilde{u}_R}$ (centre right), $m_{\tilde{t}_1}$ (bottom left) and $m_{\tilde{\tau}_1}$ (bottom right). The solid blue line in each panel corresponds to the current analysis of the supersymmetric SU(5) model including LHC Run 2 data at 13 TeV, the dashed blue line shows the result of an SU(5) fit in which the LHC 13-TeV results are not included, and the solid grey line corresponds to ‘fake’ NUHM2-like results obtained by selecting a subset of the SU(5) sample with $m_5/m_{10} \in [0.9, 1.1]$, which we discuss in more detail later⁹

The current SU(5) fit exhibits minima of χ^2 at masses $\lesssim 2.5$ TeV: $m_{\tilde{g}} \simeq 2600$ GeV, com-

mon squark mass $m_{\tilde{q}} \simeq 2200$ GeV, $m_{\tilde{u}_R}$, $m_{\tilde{d}_R}$, $m_{\tilde{t}_1} \simeq 2200$ GeV and $m_{\tilde{\tau}_1} \simeq 540$ GeV, followed by a rise at higher mass towards a plateau with $\Delta\chi^2 \lesssim 2$. The minimum is relatively sharp for $m_{\tilde{g}}$, $m_{\tilde{q}}$ and $m_{\tilde{\tau}_1}$, whereas it is broader for $m_{\tilde{t}_1}$. The exact values are listed in Table 4 and depicted in Fig. 11. In this figure we also indicate decay BRs exceeding 20% by dashed lines. Fig. 12 displays the 68 and 95% CL ranges for the Higgs and sparticle masses in the supersymmetric SU(5) model as darker and lighter coloured bands, with the best-fit values shown as blue lines.

Concerning future e^+e^- colliders, one can see that many best-fit masses of electroweak particles are at ~ 500 GeV, offering the possibility of pair production at a collider with $\sqrt{s} \sim 1$ TeV, as envisaged for the final stage of the ILC [76,77]. Going to higher centre-of-mass energies, e.g., $\sqrt{s} \lesssim 3$ TeV [77,78] as anticipated for CLIC, significant fractions of the 68% CL ranges

⁹The $\Delta\chi^2$ functions for the NUHM2 subsample are calculated relative to its minimum χ^2 , which is ~ 0.4 higher than the minimum χ^2 for the full SU(5) sample.

Figure 9. The $(M_A, \tan\beta)$ plane in the SUSY SU(5) GUT model. The line colours and shadings are the same as in Fig. 4.

Table 4

Particle masses [at the best-fit point in the SUSY SU(5) GUT model (in GeV units)].

of electroweak sparticle masses can be covered.

As already noted, a novel feature of the SUSY SU(5) GUT model with $(m_5 \neq m_{10})$ is that the \tilde{u}_R and \tilde{c}_R may be much lighter than the other squarks. This leads to the possibility of a $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation strip where $m_{\tilde{u}_R}$ and $m_{\tilde{c}_R} \sim 500$ GeV, which is visible as a second local minimum of χ^2 with $\Delta\chi^2 < 4$ in the centre right panel of Fig. 10.

We have checked specifically whether this strip

is allowed by the available LHC constraints. To this end, we verified using the `Atom` simulation code that points along this strip are consistent with the published constraints from the LHC 8-TeV data. We have also checked that this strip is consistent with the preliminary simplified model search for $\tilde{q}\tilde{q} + \tilde{q}\tilde{q}$ at 13 TeV reported by CMS. The left panel of Fig. 13 displays as a solid/dashed blue line the one-dimensional χ^2 function for $m_{\tilde{u}_R} - m_{\tilde{\chi}_1^0}$ including/omitting the 13-TeV data

Figure 10. The χ^2 likelihood functions in the SUSY $SU(5)$ GUT model (blue lines) for the gluino mass (top left panel), the left-handed squark mass (top right panel), the right-handed down squark mass (centre left panel), the right-handed up squark mass (centre right panel), the lighter stop squark mass (lower left panel) and the lighter stau slepton mass (lower right panel). The dashed blue lines shows the result of omitting the LHC 13-TeV constraints, and the grey lines represent ‘fake’ NUHM2 results obtained by selecting a subset of the $SU(5)$ sample with $m_5/m_{10} \in [0.9, 1.1]$.

Figure 11. *The spectrum at the best-fit point in the SUSY SU(5) GUT model. Decay branching ratios exceeding 20% are denoted by dashed lines.*

Figure 12. *The 68 and 95% CL ranges of masses we obtain for the current fit in the supersymmetric SU(5) model, shown in dark and light orange respectively. The best-fit point is represented by blue lines.*

(the corresponding lines for $m_{\tilde{c}_R} - m_{\tilde{\chi}_1^0}$ are very similar), and the right panel of Fig. 13 shows the region of the $(m_{\tilde{u}_R}, m_{\tilde{\chi}_1^0})$ plane where $\Delta\chi^2 < 5.99$, i.e., allowed at the 95% CL. We find that $\sigma(\tilde{q}\tilde{q} + \tilde{q}\tilde{q}) < 0.1$ pb in this region, whereas the cross section upper limit as given in [5] is $\gtrsim 1$ pb. We conclude that this simplified model search does not affect the likelihood in this $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation strip region. However, it will be explored further by future LHC data with in-

creased luminosity.

Another novel feature of the SUSY SU(5) GUT model is visible in Table 4 and Fig. 11. Having $m_5 \neq m_{10}$ allows the possibility of strong mixing between the $\tilde{\tau}_R$ in the **10** representation and the $\tilde{\tau}_L$ in the **5** representation. For example, at the best-fit point the $\tilde{\tau}_1$ is an almost equal mixture of $\tilde{\tau}_L$ and $\tilde{\tau}_R$:

$$\tilde{\tau}_1 = 0.70 \tilde{\tau}_L + 0.72 \tilde{\tau}_R. \quad (15)$$

Figure 13. *Left panel:* the χ^2 likelihood function in the SUSY SU(5) GUT model for $m_{\tilde{u}_R} - m_{\tilde{\chi}_1^0}$ in the $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation strip region (the solid/dashed line includes/omits the 13-TeV LHC data). *Right panel:* the region of the $(m_{\tilde{u}_R}, m_{\tilde{\chi}_1^0})$ plane where $\Delta\chi^2 < 5.99$.

This large mixing explains the level repulsion $\Delta m \simeq 200$ GeV between the $\tilde{\tau}_1$ and $\tilde{\tau}_2$ seen in Table 4, which is much larger than the splitting $\Delta m \simeq 50$ GeV between the almost unmixed $\tilde{e}_1 \sim \tilde{e}_R$ and $\tilde{e}_2 \sim \tilde{e}_L$ that is also seen in Table 4.

We show in Fig. 14 the contribution to the global χ^2 function of $(g-2)_\mu$ (in teal), as a function of m_5 (left panel), m_{10} (middle panel) and $m_{1/2}$ (right panel). In each case, there is a well-defined minimum that is lower than the plateau at large mass values by $\Delta\chi^2 \gtrsim 2$. In contrast, the contributions to the global χ^2 function of the other observables are relatively featureless over large ranges of m_5 , m_{10} and $m_{1/2}$, with the exception of the contribution from the LHC 13-TeV data (mainly due to the \cancel{E}_T constraint), which rises sharply at low $m_{1/2}$, as shown in red in the right panel of Fig. 14. Because we profile over the other parameters, this does not have much impact on the dependence of χ^2 on m_5 and m_{10} , as seen in the left and middle panels. The well-defined minima seen in the $(g-2)_\mu$ contributions in the left and middle panels of Fig. 14 occur at quite small values of m_5 and m_{10} , reflecting the fact that $(g-2)_\mu$ is sensitive to the soft symmetry-breaking contributions to the masses of both the $\tilde{\mu}_L$ and the $\tilde{\mu}_R$. These are m_5 and m_{10} , respec-

tively, so maximizing the SUSY contribution to $(g-2)_\mu$ and thereby minimizing the $(g-2)_\mu$ contribution to χ^2 prefers small values of both m_5 and m_{10} . Similarly, the SUSY contribution to $(g-2)_\mu$ is suppressed for large gaugino masses, explaining the aversion to large $m_{1/2}$ seen in the right panel of Fig. 14.

The principal contributions to the global χ^2 function at the best-fit point for the SUSY SU(5) GUT model are given in Table 5, and the corresponding pulls at the best-fit point are displayed graphically in Fig. 15. Apart from $(g-2)_\mu$, the other contributions deserving of comment include the following. The large contribution from `HiggsSignals` reflects the large number of channels considered, and has negligible variation for most of the points in our sample. We note that $A_{\text{FB}}(b)$ makes a contribution that is not much smaller than that of $(g-2)_\mu$ at the best-fit point, and that A_{LR}^e and σ_{had}^0 also make relatively large contributions to the global χ^2 function. These observables reflect the residual tensions in the electroweak precision observables at the Z peak, which are present in the SM and the SUSY SU(5) GUT model is unable to mitigate.

In order to compare the quality of the SU(5) fit to the results of previous MasterCode analyses of

Figure 14. The χ^2 contributions of $(g-2)_\mu$ (teal) and LHC 13-TeV data (red) in the SUSY SU(5) GUT model, as functions of m_5 (left panel), m_{10} (middle panel) and $m_{1/2}$ (right panel).

Table 5

The principal χ^2 contributions of observables at the best-fit point in the SUSY SU(5) GUT model, together with the total χ^2 function.

competing models [9], we follow the prescription used there of subtracting from the total χ^2 given in Table 5 and Fig. 15, namely 100.34, the χ^2 contributions originating from HiggsSignals [62], which dominate the global χ^2 function and would bias the analysis. Fig. 15 lists 36 separate contributions to the total χ^2 function. The first 3 (m_t , M_Z , and $\Delta\alpha_{\text{had}}^{(5)}(M_Z)$) are treated as nuisance parameters and the two LHC MET constraints at 8 and 13 TeV are applied as a single constraint. Omitting the HiggsSignals constraints in our determination of the number of degrees of freedom leaves 30 constraints, with 7

parameters for the SU(5) model and hence 23 degrees of freedom. The χ^2 contributions from the relevant constraints sum to 32.39, corresponding to a χ^2 probability of 9%. This can be compared with the χ^2 probability values of 11, 12, 11 and 31% found in [9] for the CMSSM, NUHM1, NUHM2 and pMSSM10, respectively, using LHC Run 1 constraints. However, as in [9], we stress that these χ^2 probabilities are only approximate since, for example, they neglect correlations between the observables. A more complete treatment using toys is beyond the scope of this work.

There are a couple of important corollaries to

Figure 15. The χ^2 pulls for different observables at the best-fit point in the SUSY SU(5) model.

this observation, one concerning $m_{\tilde{t}_1}$. It is sensitive to A_0 as well as the soft SUSY-breaking contributions to the \tilde{t}_L and \tilde{t}_R mass parameters (which are both given by m_{10} in the SUSY SU(5) GUT model). Since A_0 is relatively poorly determined, the χ^2 minimum for $m_{\tilde{t}_1}$ is relatively shallow, as seen in the lower left panel of Fig. 10.

The second observation concerns the sign of μ . All our analysis has been for $\mu > 0$, which is the sign capable of mitigating the discrepancy between the experimental value of $(g-2)_\mu$ and the SM prediction. For $\mu < 0$, the large-mass plateau would have a similar height as in Fig. 14, but the χ^2 function would rise monotonically at low values of m_5 , m_{10} and $m_{1/2}$, instead of featuring a dip. Thus, the $\mu < 0$ possibility would be disfavoured by $\Delta\chi^2 \gtrsim 2$, and the global minimum would lie at large masses and be ill defined.

The χ^2 distributions for some more observables are shown in Fig. 16. We see that the minima for $m_{\tilde{\chi}_1^0}$ (upper left panel) and $m_{\tilde{\chi}_1^\pm}$ (upper right panel) are quite well defined, mirroring the structure in the χ^2 function for $m_{\tilde{\tau}_1}$ shown in the lower right panel of Fig. 10. The preference for a (very) small $\tilde{\tau}_1 - \tilde{\chi}_1^0$ mass difference is seen in the lower left panel of Fig. 16, and reflects the fact, commented on in connection with many previous figures, that the best-fit point and much of the 68% CL region lies in the $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation region. On the other hand, no preference for a small $m_{\tilde{t}_1} - m_{\tilde{\chi}_1^0}$ mass difference can be observed, as seen in the lower right plot of Fig. 16, reflecting the fact that stop coannihilation does not play a significant role.

The $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ coannihilation region is prominent in the previous figures, and also contains parameter sets that are preferred at the 68% CL. Hence a small $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ mass difference is also allowed at the $\Delta\chi^2 \gtrsim 1$ level, as seen in the left panel of Fig. 17, although the best-fit point has $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} \sim 470$ GeV. However, values of the $\tilde{\chi}_1^\pm$ lifetime that are allowed at the 95% CL are all too short to provide a long-lived particle signal, as seen in the right panel of Fig. 17.¹⁰

We now discuss the one-dimensional likelihood

¹⁰For conditions to have a long-lived $\tilde{\chi}_1^\pm$ with a bino-like LSP: see, e.g., [79].

Figure 16. The χ^2 likelihood functions in the SUSY SU(5) GUT model for the $\tilde{\chi}_1^0$ mass (upper left panel), the $\tilde{\chi}_1^\pm$ mass (upper right panel), the $\tilde{\tau}_1 - \tilde{\chi}_1^0$ mass difference (lower left panel) and the $\tilde{t}_1 - \tilde{\chi}_1^0$ mass difference (lower right panel). The dashed blue lines shows the result of omitting the LHC 13-TeV constraints, and the grey lines represent ‘fake’ NUHM2 results obtained by selecting a subset of the SU(5) sample with $m_5/m_{10} \in [0.9, 1.1]$.

functions for electroweak precision observables and observables in the flavour sector. The upper left panel of Fig. 18 shows that for $(g-2)_\mu$. We see that the global minimum occurs for $\Delta(g-2)_\mu \simeq 0.4 \times 10^{-9}$, with $\Delta\chi^2 \lesssim -2$ compared to the case $\Delta(g-2)_\mu = 0$. We see again that the SUSY SU(5) GUT model is able to mitigate slightly the discrepancy between the SM and the measurement of $(g-2)_\mu$, although it does not provide a substantial improvement over the SM prediction.

As for M_h , as shown in the upper right panel of Fig. 18 the χ^2 function is minimized close to

the nominal experimental value, and is quite symmetric, showing no indication of any tension in the SUSY SU(5) GUT model fit. Likewise, the best-fit value of M_W (lower left panel of Fig. 18) is highly compatible with the experimental measurement, and that for $\text{BR}(B_{s,d} \rightarrow \mu^+\mu^-)$ (lower right panel) is very close to the SM prediction, and hence also compatible with the experimental measurement. We note that, whereas values of $\text{BR}(B_{s,d} \rightarrow \mu^+\mu^-)$ that are slightly larger than the SM value are possible, smaller values are strongly disfavoured in the SUSY SU(5) GUT

Figure 17. The χ^2 likelihood functions in the SUSY SU(5) GUT model for the $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ mass (left panel) and the $\tilde{\chi}_1^\pm$ lifetime (right panel). The dashed blue lines shows the result of omitting the LHC 13-TeV constraints, and the grey lines represent ‘fake’ NUHM2 results obtained by selecting a subset of the SU(5) sample with $m_5/m_{10} \in [0.9, 1.1]$.

model.

7. Higgs Branching Ratios

We present in Fig. 19 the one-dimensional likelihood functions for the ratios of supersymmetric SU(5) and SM predictions for the BRs of $h \rightarrow \gamma\gamma$ (left panel), $h \rightarrow ZZ^*$ (middle panel)¹¹ and $h \rightarrow gg$ decays (right panel). We see that in each case the preferred region in the fit corresponds to a prediction in the SU(5) model that deviates from the SM case by at most a few %, whereas the present experimental uncertainties in the different coupling modifiers (employing some theory assumptions) are typically $\mathcal{O}(30)\%$ [80], and a precision of $\mathcal{O}(5 - 10\%)$ (with the same theory assumptions) can be reached by the end of the LHC programme. On the other hand, future e^+e^- colliders such as the ILC, CLIC or FCC-ee anticipate a precision at the percent level for couplings to fermions and at the permille level for couplings to massive gauge bosons [77, 81]. This offers the possibility that deviations from the SM in the SUSY SU(5) GUT model can be measured in the future.

¹¹The likelihood function for $h \rightarrow WW^*$ is very similar to that for $h \rightarrow ZZ^*$, because of custodial symmetry.

8. Comparison with Previous Results

In previous papers we have studied the CMSSM, NUHM1 and NUHM2 using the LHC 8-TeV results and earlier DM scattering constraints. None of these models are directly comparable to the supersymmetric SU(5) model studied here, which has 4 different soft SUSY-breaking scalar mass parameters, m_5, m_{10}, m_{H_u} and m_{H_d} . The most similar is the NUHM2, which has the 3 parameters $m_0 = m_5 = m_{10}, m_{H_u}$ and m_{H_d} . Here we compare the supersymmetric SU(5) results found in this paper using LHC 13-TeV data with ‘fake’ NUHM2 results obtained by selecting a subset of this SU(5) sample with $m_5/m_{10} \in [0.9, 1.1]$ (which were also displayed as grey lines in Fig. 10) and with previous NUHM2 results [8].

Fig. 20 compares the one-dimensional χ^2 likelihood functions for $m_{\tilde{g}}$ (upper left), $m_{\tilde{q}_R}$ (upper right), $m_{\tilde{t}_1}$ (lower left) and $m_{\tilde{\tau}_1}$ (lower right) found in the SU(5) model including LHC 13-TeV constraints (solid blue lines) with the restricted fake NUHM2 sample (solid grey lines) and, for comparison, results from our previous NUHM2 analysis that used only the LHC 7- and 8-TeV constraints (dashed grey lines) [8]. We see here and in Fig. 10 that the restricted ‘fake’ NUHM2

Figure 18. The χ^2 likelihood functions in the SUSY SU(5) GUT model for $(g-2)_\mu/2$ (upper left panel), M_h (upper right panel), M_W (lower left panel), and $\text{BR}(B_{s,d} \rightarrow \mu^+ \mu^-)$ (lower right panel). The dashed blue lines shows the result of omitting the LHC 13-TeV constraints, and the grey lines represent ‘fake’ NUHM2 results obtained by selecting a subset of the SU(5) sample with $m_5/m_{10} \in [0.9, 1.1]$.

sample exhibits, in general, best-fit masses that are similar to those found in the full SU(5) sample. The most noticeable differences are that lower masses are disfavoured in the restricted sample relative those in the full SU(5) model, indicating that the latter has some limited ability to relax the NUHM2 lower bounds on sparticle masses, e.g., at the 95% CL. The previous NUHM2 analysis [8] also yielded similar best-fit masses but, as could be expected, gave 95% CL lower limits on sparticle masses that were further relaxed. Similar features can also be observed in Figs. 16 - 19, where we have also included the ‘fake’ NUHM2 subsample.

Restricting further our SU(5) to mimic the

NUHM1, let alone the CMSSM, is not useful because of the increased sampling uncertainties in such restricted samples. However, we showed in [8] that our NUHM2 LHC 7- and 8-TeV results for the exhibited sparticle masses were broadly similar to those for the NUHM1 and the CMSSM [7], and we expect the impacts of the LHC 13-TeV data on these models to be comparable to that in the NUHM2.

Finally, we ask whether or not there is a significant improvement in the SU(5) fit compared to that in the NUHM2 subsample, thanks to the additional parameter (m_5 and m_{10} replacing m_0). The NUHM2 subsample has a total $\chi^2 = 100.8$, which is reduced to 32.8 when we remove the con-

Figure 19. The χ^2 likelihood functions for the ratios of the SUSY $SU(5)$ and SM predictions for the BRs of $h \rightarrow \gamma\gamma$ (left panel), $h \rightarrow ZZ^*$ (middle panel) and $h \rightarrow gg$ decays (right panel). The dashed blue lines shows the result of omitting the LHC 13-TeV constraints, and the grey lines represent ‘fake’ NUHM2 results obtained by selecting a subset of the $SU(5)$ sample with $m_5/m_{10} \in [0.9, 1.1]$.

tributions from `HiggsSignals`, as discussed earlier. It should be noted that the NUHM2 subsample is statistically significantly smaller than that of the $SU(5)$ sample. The quoted NUHM2 χ^2 represents only an upper bound on the χ^2 of the best-fit point that would be found in a more complete sample of the NUHM2. Since the NUHM2 model has one less parameter than the $SU(5)$ model, it has 24 degrees of freedom, and its χ^2 probability is 11%. According to the Wilks test, the probability that the data are represented better by the $SU(5)$ model than by the NUHM2 subsample is 50%, i.e., there is no evidence that the extra parameter of $SU(5)$ provides a significant improvement.

9. The Possibility of a Long-Lived $\tilde{\tau}_1$

The possibility of a very small $\tilde{\tau}_1 - \tilde{\chi}_1^0$ mass difference opens up the possibility that the $\tilde{\tau}_1$ might have a long lifetime, as discussed in the contexts of the CMSSM, NUHM1 and NUHM2 in [10]. This would occur if $m_{\tilde{\tau}_1} - m_{\tilde{\chi}_1^0} < m_\tau$. As seen in the lower left panel of Fig. 16, the best-fit point has a mass difference ~ 20 GeV, outside this range, but $m_{\tilde{\tau}_1} - m_{\tilde{\chi}_1^0} < m_\tau$ is allowed with $\Delta\chi^2 \sim 1$. In Fig. 21 we analyze the lifetime of the $\tilde{\tau}_1$. We see in the upper left panel of Fig. 21 that there is essentially no χ^2 penalty for 10^{-9} s $\lesssim \tau_{\tilde{\tau}_1} \lesssim 10^{-2}$ s, with lifetimes $\sim 10^{-10}$ s

and $\lesssim 10^3$ s allowed with $\Delta\chi^2 \lesssim 1$. Distinguishing a separated-vertex signature at the LHC would be challenging for smaller values of $\tau_{\tilde{\tau}_1}$, and there would be significant disruption of the successful conventional Big Bang nucleosynthesis calculations for $\tau_{\tilde{\tau}_1} \gtrsim 10^3$ s [82].

The upper right plot of Fig. 21 compares the $\tilde{\tau}_1$ lifetime with its mass. A striking feature is the separation of the 68% CL region into two bands: a broad one at smaller $m_{\tilde{\tau}_1}$ and a narrower band at $m_{\tilde{\tau}_1} \simeq 2000$ GeV. These bands are separated by a strip with 1300 GeV $\lesssim m_{\tilde{\chi}_1^0} \lesssim 2000$ GeV where a long-lived $\tilde{\tau}_1$ is still allowed at the 95% CL, but at the 68% CL the τ_1 lifetime falls outside the range displayed.

The lower panels of Fig. 21 display the regions of the $(m_5, m_{1/2})$ (left) and $(m_{10}, m_{1/2})$ (right) planes in the SUSY $SU(5)$ GUT model where the lowest- χ^2 points have 10^{-10} s $< \tau_{\tilde{\tau}_1} < 10^3$ s. The colour-coding indicates the lifetimes of these points, as indicated in the legends. The contours for $\Delta\chi^2 < 2.30(5.99)$ relative to the best-fit point in our sample are shown as solid red and blue lines, respectively. One can see that larger lifetimes occur all over the displayed parameter space, with a slight preference for larger m_5 or m_{10} values.

Figure 20. The one-dimensional χ^2 likelihood functions for the full $SU(5)$ sample (solid blue lines) and in the restriction of the $SUSY SU(5)$ GUT model sample to $m_5/m_{10} \in [0.9, 1.1]$ (solid grey lines) compared to those in our previous $NUHM2$ analysis [8] (dashed grey lines) for $m_{\tilde{g}}$ (upper left panel), $m_{\tilde{q}}$ (upper right panel), $m_{\tilde{t}_1}$ (lower left panel), and $m_{\tilde{\tau}_1}$ (lower right panel).

10. Direct Dark Matter Detection

As already mentioned, the PandaX-II experiment [27] has recently published results from its first 98.7 days of data, which currently provide the most stringent upper limits on the spin-independent DM scattering cross section on protons, σ_p^{SI} . In parallel, the LUX Collaboration [28] has presented preliminary constraints on σ_p^{SI} from 332 days of data. We have combined these two constraints on σ_p^{SI} into a single experimental likelihood function, which we have then convoluted with an estimate of the theoretical uncertainty

in the calculation of σ_p^{SI} , as described in [10], to constrain the $SUSY SU(5)$ GUT parameter space. This constraint has been used in obtaining the global fit whose results we have presented in the previous Sections. Here we discuss the future prospects for direct DM detection in light of our global fit.

Fig. 22 displays our results for the $SUSY SU(5)$ GUT model in the $(m_{\tilde{\chi}_1^0}, \sigma_p^{\text{SI}})$ plane. The combined PandaX-II/LUX constraint (black line) establishes a 95% CL that reaches $\sigma_p^{\text{SI}} \simeq 2 \times 10^{-46} \text{ cm}^2$ for $m_{\tilde{\chi}_1^0} = 50 \text{ GeV}$ and $\simeq 10^{-45} \text{ cm}^2$ for $m_{\tilde{\chi}_1^0} = 500 \text{ GeV}$, providing the upper bound-

Figure 21. *Upper left panel: The global χ^2 function in the SUSY SU(5) GUT model as a function of the $\tilde{\tau}_1$ lifetime. Upper right panel: The $(m_{\tilde{\tau}_1}, \tau_{\tilde{\tau}_1})$ plane, shaded according to the values of $\tau_{\tilde{\tau}_1}$, as indicated. Lower panels: The $(m_5, m_{1/2})$ and $(m_{10}, m_{1/2})$ planes, coloured according to the values of $\tau_{\tilde{\tau}_1}$. The 68% and 95% CL contours in these three planes are coloured red and blue, respectively.*

ary of the 95% CL region in the $(m_{\tilde{\chi}_1^0}, \sigma_p^{\text{SI}})$ plane seen in Fig. 22. We see that there are regions favoured at the 68% CL that lie relatively close to this boundary, whereas the main 68% CL region and the best-fit point have smaller values of σ_p^{SI} . We also note that the H/A funnel and $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ DM mechanisms and their hybridization favour values of σ_p^{SI} that are relatively close to the PandaX-II/LUX boundary, whereas the $\tilde{\tau}_1 - \tilde{\chi}_1^0$ mechanism and its hybridization with the H/A funnel favour smaller values of σ_p^{SI} .

We also display in Fig. 22 the projected 95% exclusion sensitivity of the future LUX-Zepelin

(LZ) experiment (solid purple line) [83] and the astrophysical neutrino ‘floor’ (dashed orange line) [84, 85], below which astrophysical neutrino backgrounds dominate (yellow region). We see that much of the $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation region and the region of its hybridization with the H/A funnel lie below the projected sensitivity of the LZ experiment, and substantial portions of them also lie below the neutrino ‘floor’. On the bright side, however, we recall that the $\tilde{\tau}_1 - \tilde{\chi}_1^0$ region, in particular, lies at relatively small values of m_5, m_{10} and $m_{1/2}$, offering greater prospects for detection at the LHC than, e.g., the $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ region, so

Figure 22. The $(m_{\tilde{\chi}_1^0}, \sigma_p^{\text{SI}})$ plane in the SUSY SU(5) GUT model. The solid green line is the 95% CL upper limit from the XENON100 experiment, and the dashed black solid line is the new 95% CL upper limit from the LUX experiment. The solid black line shows the 95% CL exclusion contour for our combination of the PandaX-II and LUX experiments, the solid purple line shows the projected 95% exclusion sensitivity of the LUX-ZEPHINUS (LZ) experiment, and the dashed orange line shows the astrophysical neutrino ‘floor’, below which astrophysical neutrino backgrounds dominate (yellow region). The other line colours and shadings within the 68% and 95% CL regions are the same as in Fig. 4.

there is complementarity in the prospects of the LHC and direct DM experiments for probing the SUSY SU(5) GUT model, as was noted previously for other SUSY models [10].

11. Summary and Conclusions

We have explored in this paper the experimental, phenomenological, astrophysical and cosmological constraints on the minimal SUSY SU(5) GUT model. In this scenario the GUT-scale universal soft SUSY-breaking scalar mass m_0 is replaced by independent masses for the $\mathbf{10}$ and $\bar{\mathbf{5}}$ sfermions. This flexibility introduces some features that are novel compared to the GUT-universal CMSSM, NUHM1 and NUHM2.

In general we observe that many best-fit values of the coloured particles are within the reach

of the HL-LHC, but that the preferred regions clearly extend beyond the reach of the final stage of the LHC. On the other hand, many best-fit masses of electroweak particles are at ~ 500 GeV, offering the possibility of pair production at a collider with $\sqrt{s} \sim 1$ TeV, as envisaged for the final stage of the ILC. Going to higher centre-of-mass energies, $\sqrt{s} \lesssim 3$ TeV as anticipated for CLIC, significant fractions of the 68% CL ranges of electroweak sparticle masses can be covered.

One novelty is the appearance of a $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation region that appears where $m_{\tilde{5}}^2$ is large and positive, $m_{\tilde{10}}^2$ is small and negative, and $m_{\tilde{H}_u}^2$ and $m_{\tilde{H}_d}^2$ are large and negative. On the other hand, we find that $\tilde{t}_1 - \tilde{\chi}_1^0$ coannihilation is not important in the SUSY SU(5) GUT model, nor are the focus-point region and rapid $\tilde{\chi}_1^0 \tilde{\chi}_1^0$ annihilation via direct-channel h and Z poles. We

have checked that the $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ coannihilation region is not yet excluded by searches for \cancel{E}_T events at the LHC, because the production rate is reduced compared to the case where all 8 squarks are mass degenerate and the small $\tilde{u}_R/\tilde{c}_R - \tilde{\chi}_1^0$ mass difference suppresses this signature. However, this region may be accessible with future LHC runs.

We have also highlighted the possibility that a $\tilde{\nu}_\tau$ NLSP might have an important coannihilation role. Another novelty is the composition of the $\tilde{\tau}_1$ NLSP in a significant region of the model parameter space. In the GUT-universal CMSSM, NUHM1 and NUHM2 models, the universality of m_0 and the greater renormalization for SU(2) doublets impose a substantial mass difference between the $\tilde{\tau}_2$ and the $\tilde{\tau}_1$, with the latter being predominantly a $\tilde{\tau}_R$. However, in the SUSY SU(5) GUT model with $m_5 \neq m_{10}$, the $\tilde{\tau}_R$ and $\tilde{\tau}_L$ may have similar masses, and the off-diagonal entries in the $\tilde{\tau}$ mass matrix may cause large mixing and repulsion between the $\tilde{\tau}_1$ and $\tilde{\tau}_2$ masses.

On the other hand, one experimental signature that is shared by the SUSY SU(5) GUT model and GUT-universal models is the possible appearance of a long-lived (metastable) $\tilde{\tau}_1$. This is a feature of a significant fraction (but not all) of the $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation region.

The prospects for direct DM detection are mixed: they are relatively good in the $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ coannihilation region, but less promising in the rapid H/A annihilation and hybrid regions, though potentially detectable in the planned LUX-Zepelin experiment. On the other hand, the $\tilde{\tau}_1 - \tilde{\chi}_1^0$ coannihilation region probably lies beyond the reach of this experiment, as does part of the hybrid region. Indeed, portions of these regions lie below the neutrino ‘floor’. On the other hand, substantial parts of these regions are accessible to LHC searches for long-lived particles and \cancel{E}_T .
