Single-term Veneziano dual amplitudes with nondegenerate Regge slopes are examined in detail. Factorization of parent resonance residues and the equal-spacing rule extracted from the universal-slope case are used to determine all the leading-meson-trajectory parameters in terms of that of the ρ . Relations between nondegenerate slopes and SU(4)-symmetry-breaking effects are discussed. The predicted meson mass spectra and the partial decay widths into two pseudoscalars are shown to agree well with data for the cases in which data exist.

I. INTRODUCTION

Investigations of the properties of charmed mesons¹ in the duality scheme have been carried out by several authors. One framework used is the concise dual Veneziano model² which has been successful in dealing with ordinary particles. In order to accommodate the new particles, a modification of the Veneziano model is needed, and this modification takes mainly two forms: (a) incorporating the SU(4) structure in the original Veneziano model with a universal Regge slope,³ and (b) modifying the original framework to allow different slopes for different meson trajectories.⁴

Scheme (a) is supported by the mass-quantization relation⁵ $\alpha_{D^*}(m_{D^*}^2) = \frac{1}{2}$ (Ref. 3) satisfied by the D trajectory with the universal slope $\alpha'_{D^*} = \alpha'_\rho = \frac{1}{2}(m_\rho^2 - m_\pi^2)^{-1}$. This approach leads to the generalization of the nonet mass formula to SU(4) including vector and pseudoscalar mesons, but it has difficulty in accommodating the J/ψ particle. There is evidence that the J/ψ trajectory possesses a smaller slope. If we take $\psi'(3.7)$ as its first daughter, then the slope is $\alpha'_J \approx 0.25$, while taking $\psi'(3.7)$ as the second daughter gives $\alpha'_J \approx 0.5$. Another estimate obtained by taking $\chi(3550)$ as the 2^{++} exchange degenerate partner of J/ψ gives $\alpha'_J \approx 0.33$. The last value of α'_J leads to $m_{\eta_c} = 2.84$ GeV, if the Ademollo-Veneziano-Weinberg mass-quantization rule⁵ $\alpha_J(m_{\eta_c}^2) = \frac{1}{2}$ is used,⁶ where η_c is the $c\bar{c} 0^{-+}$ state. In all these cases the slope of the J/ψ trajectory is much smaller than that of the ρ trajectory, $\alpha'_\rho \approx 0.9$ GeV⁻².

Scheme (b) is motivated by the drastically different mass scales of the charmed and ordinary mesons which are expected to give rise to appreciable higher-order symmetry-breaking effects.

One of the possible consequences is that coupling constants may significantly deviate from their [SU(4)] symmetry values. This in turn will require that the universality of the trajectory slope parameters be broken in Veneziano amplitudes, as slopes and coupling constants are related there. The presence of higher-order symmetry-breaking effects in the charmed SU(3) sector of SU(4) can be seen from the poorly satisfied charmed nonet mass formula, e.g. $m_{J^2} + m_{\rho^2} = 2m_{D^*}^2$, which is good only to 20%.

The Veneziano formula with nondegenerate slopes has a serious problem. It leads to an exponentially increasing scattering amplitude for large fixed angle at high energy.⁷ A way out of this difficulty was proposed recently by Igi,⁸ who suggested that the phenomenon of nondegenerate slopes occurs at low energy and that at high energy, where the Regge asymptotic expansion is applied, all the slopes become universal. Although such a proposal is very difficult to implement analytically, it provides an attractive phenomenological framework tailored to the resonance region and may be useful in the description of certain aspects of the new particles.

Many interesting relations have been derived in terms of single-term Veneziano amplitudes in the case of degenerate slopes, such as the nonet mass relations involving vector (tensor) and pseudoscalar mesons,² the equal-spacing rule,⁹ the mass-quantization rule,⁵ factorization of the parents and the first daughters,¹⁰ etc. (They are not all independent.) Further, the couplings of two pseudoscalar mesons to all the particles on a leading trajectory are related to each other, and these couplings of the particles of the same spin, but lying on different trajectories, satisfy SU(3) symmetry.

Undoubtedly, some of these results will no longer be true in the case of nondegenerate slopes.

In this article, restricting ourselves essentially to the resonance region, we study in detail the properties of the Veneziano model with nondegenerate slopes. We examine the factorization property and propose a scheme to express all the slopes of the leading meson trajectories in terms of, say, that of the ρ trajectory, and thereby determine them unambiguously.¹¹

In Sec. II we review briefly some of the results known in the case of universal slopes. In particular, we put the factorization conditions in a form such that we can adopt them to the case of nondegenerate slopes. Section III treats the nondegenerate slopes. In Sec. IV, we present a discussion of the symmetry-breaking effects and calculate the meson mass spectra and the partial widths of the leading $1^-, 2^+, 3^-$ mesons decaying into two pseudoscalar mesons. We also predict the mass of the F^* . Our conclusions are given in Sec. V.

II. FACTORIZATION

To put things in perspective, let us recapitulate some of the known results involving only the old mesons. Consider the following s -channel processes with their single-term Veneziano amplitudes:

$$A(\pi^+\pi^-\rightarrow\pi^+\pi^-)=\lambda^\pi V_{\rho\rho}(s,t), \quad (2.1a)$$

$$A(\pi^+\pi^-\rightarrow K^+K^-)=\lambda^{\pi K} V_{\rho K^*}(s,t), \quad (2.1b)$$

$$A(K^+K^-\rightarrow K^+K^-)=\frac{1}{2}\lambda^K [V_{\rho\phi}(s,t)+V_{\phi\rho}(s,t) \\ +V_{\omega\phi}(s,t)+V_{\phi\omega}(s,t)], \quad (2.1c)$$

where

$$V_{ab}(s,t)\equiv\frac{\Gamma(1-\alpha_a(s))\Gamma(1-\alpha_b(t))}{\Gamma(1-\alpha_a(s)-\alpha_b(t))},$$

and α_ρ , α_ω , α_{K^*} , and α_ϕ represent the exchange-degenerate ρ - f - ω - A_2 , K^* - K^{**} , and ϕ - f' trajectories.

We first fix the normalization constants λ^π , $\lambda^{\pi K}$, and λ^K by considering Regge expansions in the t channel for large t and small s . Following Igi,⁸ we assume that when $t\rightarrow\infty$, the slopes of the trajectories contributing to the t channel reduce to a universal value. The ρ trajectory exchanged in the

s channel leads to

$$\lambda^\pi\Gamma(1-\alpha_\rho(s))(-\alpha'_\rho t)^{\alpha_\rho(s)}\left(1+O\left(\frac{1}{t}\right)\right), \quad (2.2a)$$

$$\lambda^{\pi K}\Gamma(1-\alpha_\rho(s))(-\alpha'_{K^*}t)^{\alpha_\rho(s)}\left(1+O\left(\frac{1}{t}\right)\right), \quad (2.2b)$$

$$\frac{1}{2}\lambda^K\Gamma(1-\alpha_\rho(s))(-\alpha'_\phi t)^{\alpha_\rho(s)}\left(1+O\left(\frac{1}{t}\right)\right), \quad (2.2c)$$

for the three processes, respectively. Since $\alpha'_\rho = \alpha'_{K^*} = \alpha'_\phi$ in the t channel for $t\rightarrow\infty$, factorization gives

$$\lambda^\pi\lambda^K=2(\lambda^{\pi K})^2. \quad (2.3)$$

If we further argue that the ρ residues take SU(3)-symmetric values, we have

$$\lambda^K=\lambda^{\pi K}=\frac{1}{2}\lambda^\pi. \quad (2.4)$$

We need only Eq. (2.3) in this and in the next section.

Next we consider the factorization constraints at the s -channel resonances, where the slopes are not necessarily equal. For $s\rightarrow s_L$ and $\alpha_\rho(s_L)=L$ we obtain

$$A(\pi^+\pi^-\rightarrow\pi^+\pi^-)\rightarrow\frac{\lambda^\pi}{\alpha'_\rho(s-s_L)}\frac{1}{\Gamma(L)} \\ \times\prod_{n=0}^{L-1}(\alpha_\rho(t)+n), \quad (2.5a)$$

$$A(\pi^+\pi^-\rightarrow K^+K^-)\rightarrow\frac{\lambda^{\pi K}}{\alpha'_\rho(s-s_L)}\frac{1}{\Gamma(L)} \\ \times\prod_{n=0}^{L-1}(\alpha_{K^*}(t)+n), \quad (2.5b)$$

$$A(K^+K^-\rightarrow K^+K^-)\rightarrow\frac{\lambda^K}{\alpha'_\rho(s-s_L)}\frac{1}{\Gamma(L)} \\ \times\prod_{n=0}^{L-1}(\alpha_\phi(t)+n). \quad (2.5c)$$

In Eqs. (2.5a) and (2.5b), the even- and odd-spin parents and their daughters contribute to the $I=0$ and $I=1$ amplitudes, respectively. Therefore at each integer l ($0\leq l\leq L$), there is only one particle contributing. In Eq. (2.5c), there are two particles contributing to each value of l , the one with $I=0$ and the other with $I=1$. This gives rise to a factor $\frac{1}{2}$ to the resonance residues in the reaction $K^+K^-\rightarrow K^+K^-$. Writing Eqs. (2.5) in terms of states with definite angular momenta, we have

$$A(\pi^+\pi^-\rightarrow\pi^+\pi^-)\rightarrow\frac{\lambda^\pi}{\alpha'_\rho(s-s_L)}\frac{1}{\Gamma(L)}\left[(2\alpha'_\rho k_\pi^2)^L\frac{2^L[\Gamma(L+1)]^2}{\Gamma(2L+1)}P_L(z_s)+a_\pi\frac{2^{L-1}[\Gamma(L)]^2}{\Gamma(2L)}(2\alpha'_\rho k_\pi^2)^{L-1}P_{L-1}(z_s)+\dots\right]. \quad (2.6)$$

To obtain the expressions for $A(\pi^+\pi^-\rightarrow K^+K^-)$ and $A(K^+K^-\rightarrow K^+K^-)$, we make the substitution $(\lambda^\pi, \alpha'_\rho k_\pi^2, a_\pi) \rightarrow (\lambda^{\pi K}, \alpha'_{K^*} k_\pi k_K, a_{\pi K})$ and $(\lambda^K, \alpha'_\phi k_K^2, a_K)$. The quantities k_π and k_K are the c.m. momenta of the $\pi\pi$ and $K\bar{K}$ systems, z_s is the cosine of the c.m. scattering angle, and

$$\begin{aligned} a_\pi &= L[-\tfrac{1}{2}-\tfrac{1}{2}\alpha_\rho(0)+2\alpha_\rho(m_\pi^2)], \\ a_{\pi K} &= L[-\tfrac{1}{2}-\tfrac{1}{2}\alpha_\rho(0)+\alpha_\rho(m_\pi^2)+\alpha_{K^*}(m_K^2) \\ &\quad -\tfrac{1}{2}(\alpha'_{K^*}-\alpha'_\rho)(s_L-2m_\pi^2)], \\ a_K &= L[-\tfrac{1}{2}-\tfrac{1}{2}\alpha_\rho(0)+\alpha_\rho(m_K^2)+\alpha_\phi(m_K^2) \\ &\quad -\tfrac{1}{2}(\alpha'_\phi-\alpha'_\rho)(s_L-2m_K^2)]. \end{aligned} \quad (2.7)$$

Factorization at the parent level together with Eq. (2.3) gives¹²

$$\alpha'_\rho \alpha'_\phi = \alpha_{K^*}^2. \quad (2.8)$$

Factorization of the first daughter can be achieved in the case of the degenerate slopes if the following conditions are satisfied:

$$m_\rho^2 - m_\pi^2 = m_{K^*}^2 - m_K^2 = m_\phi^2 - 2m_K^2 + m_\pi^2, \quad (2.9)$$

which imply the nonet mass formula $m_\rho^2 + m_\phi^2 = 2m_{K^*}^2$. They can also be rewritten in terms of the trajectory parameters,

$$\alpha_\rho(m_\pi^2) = \alpha_{K^*}(m_K^2) = \alpha_\phi(2m_K^2 - m_\pi^2) \quad (2.10)$$

or

$$\alpha_\rho(0) + \alpha_\phi(0) = 2\alpha_{K^*}(0) \quad (2.11a)$$

or

$$\alpha_\rho(m_K^2) + \alpha_\phi(m_K^2) = 2\alpha_{K^*}(m_K^2). \quad (2.11b)$$

The last two expressions are equivalent forms of equal-spacing rules. Equation (2.10) gives the mass-quantization rules⁶ if it is set equal to $\frac{1}{2}$. It is clear from Eq. (2.7) that factorization of the first or subsequent younger daughters is impossible if the slopes are different.¹³ The condition analogous to Eq. (2.9) for the $\pi\pi \rightarrow \pi\pi$, $\pi\pi \rightarrow D\bar{D}$, and $D\bar{D} \rightarrow D\bar{D}$ scatterings leads to $m_\rho^2 - m_\pi^2 = m_D^2 - m_J^2 - 2m_D^2 + m_\pi^2$. The last identity is satisfied rather poorly, indicating that factorization of the first daughters cannot be maintained in general even if the slopes are degenerate, when the charmed-meson channels are included in the consideration.

III. TRAJECTORIES FOR NONDEGENERATE SLOPES

Our strategy in this section is to consider the two relations derived in the preceding section, the factorization of the trajectory slopes and the equal-spacing rules, as basic properties of the leading meson trajectories. These two relations are, of course, not on equal footing. Factorization rela-

tions [see Eq. (3.1)] can be derived from an asymptotic symmetry such as Eq. (2.4) and the factorization of parent particles irrespective of the degeneracy or the lack of degeneracy of the slopes. The equal-spacing rule, extracted from the case of degenerate slopes, is, however, an assumption. As will be seen in the next section, the good predictions which follow indicate the validity of this assumption. From the above argument, we can write the factorization conditions as

$$\begin{aligned} \alpha'_\rho \alpha'_\phi &= \alpha_{K^*}^2, \\ \alpha'_\rho \alpha'_J &= \alpha_{D^*}^2, \\ \alpha'_\phi \alpha'_J &= \alpha_{F^*}^2, \end{aligned} \quad (3.1)$$

and the equal-spacing rules as

$$\begin{aligned} \alpha_\rho(0) + \alpha_\phi(0) &= 2\alpha_{K^*}(0), \\ \alpha_\rho(0) + \alpha_J(0) &= 2\alpha_{D^*}(0), \\ \alpha_\phi(0) + \alpha_J(0) &= 2\alpha_{F^*}(0), \end{aligned} \quad (3.2)$$

which we generalized from Eq. (2.11a). The generalization of Eq. (2.11b) is

$$\begin{aligned} \alpha_\rho(m_K^2) + \alpha_\phi(m_K^2) &= 2\alpha_{K^*}(m_K^2), \\ \alpha_\rho(m_D^2) + \alpha_J(m_D^2) &= 2\alpha_{D^*}(m_D^2), \\ \alpha_\phi(m_F^2) + \alpha_J(m_F^2) &= 2\alpha_{F^*}(m_F^2). \end{aligned} \quad (3.3)$$

Equations (3.2) and (3.3) are alternative equal-spacing rules. They cannot hold simultaneously, otherwise a common slope will result for all the trajectories. We do not propose to use relations such as (2.10), which gives directly ratios of slopes. They are inconsistent with Eq. (3.1), unless nonet types of mass formulas hold. The second and third lines of Eq. (3.1) are derived from the following sets of amplitudes, following a similar derivation as outlined in Sec. II:

$$A(\pi^+\pi^-\rightarrow \bar{D}^0 D^0) = \lambda^{\pi D} V_{\rho D^*}(s, t), \quad (3.4a)$$

$$A(D^0 \bar{D}^0 \rightarrow D^0 \bar{D}^0) = \tfrac{1}{2} \lambda^D [V_{\rho J}(s, t) + V_{J\rho}(s, t) + V_{\omega J}(s, t) + V_{J\omega}(s, t)], \quad (3.4b)$$

together with Eq. (2.1a) and $\lambda^\pi \lambda^D = 2(\lambda^{\pi D})^2$, and

$$A(K^+K^-\rightarrow \bar{D}^0 D^0) = \tfrac{1}{2} \lambda^{KD} [V_{\rho F^*}(s, t) + V_{\omega F^*}(s, t)], \quad (3.5)$$

together with Eqs. (2.1c) and (3.4b) and $\lambda^K \lambda^D = (\lambda^{KD})^2$. If we further assume asymptotic symmetry for the ρ residue, we have $\lambda^D = \lambda^{\pi D} = \frac{1}{2} \lambda^\pi$ and $\lambda^K = \lambda^D = \lambda^{KD}$.

Equations (3.1) and (3.2) give¹⁴

$$\begin{aligned} \alpha'_{K^*} &= \alpha'_\rho \frac{m_{K^*}^2}{m_\phi^2} [1 + (1 - m_\rho^2 m_\phi^2 / m_{K^*}^4)^{1/2}], \\ \alpha'_{D^*} &= \alpha'_\rho \frac{m_{D^*}^2}{m_J^2} [1 + (1 - m_\rho^2 m_J^2 / m_{D^*}^4)^{1/2}]. \end{aligned} \quad (3.6)$$

Relations similar to (3.6) can be derived from Eqs. (3.1) and (3.3) with m_ρ^2 , $m_{K^*}^2$, and m_ϕ^2 replaced by $m_\rho^2 - m_K^2$, $m_{K^*}^2 - m_K^2$, and $m_\phi^2 - m_K^2$ in α'_{K^*} , and m_ρ^2 , m_D^2 , and m_J^2 by $m_\rho^2 - m_D^2$, $m_D^2 - m_D^2$, and $m_J^2 - m_D^2$ in α'_{D^*} . Note that when the nonet mass relations, i.e., $m_\rho^2 + m_\phi^2 = 2m_{K^*}^2$ and $m_\rho^2 + m_J^2 = 2m_{D^*}^2$, become exact, Eq. (3.6) leads to degenerate slopes, $\alpha'_\rho = \alpha'_{K^*} = \alpha'_{D^*}$, etc. Equations (3.1) and (3.3) also give a universal slope if mass relations such as $m_\rho^2 - m_\pi^2 = m_{K^*}^2 - m_K^2 = m_{D^*}^2 - m_D^2$ hold.¹⁵ The nonet mass relations are assumed to hold with the presence of first-order symmetry-breaking effects, suggesting that the nondegenerate

slopes are due to symmetry-breaking effects higher than the first order.¹⁶ We shall come back to this point again in the next section. Taking $m_\rho = 0.768$, $m_{K^*} = 0.894$, $m_\phi = 1.02$, $m_{D^*} = 2.01$, and $m_J = 3.098$, all in units of GeV,¹⁷ we obtain

$$\begin{aligned}\alpha'_{K^*}/\alpha'_\rho &= 0.924, & \alpha'_\phi/\alpha'_\rho &= 0.854, \\ \alpha'_{D^*}/\alpha'_\rho &= 0.761, & \alpha'_J/\alpha'_\rho &= 0.579, \\ \alpha'_F/\alpha'_\rho &= 0.703.\end{aligned}\quad (3.7)$$

Equations (3.1) and (3.3) give ratios of slopes about 3% higher than the above. This demonstrates the stability of the equal-spacing rules.

IV. SYMMETRY BREAKING AND DECAY WIDTH

Consider the elastic scattering of two pseudoscalar mesons, $a + b \rightarrow a + b$, which is described by the following amplitude:

$$A = \lambda V_{AB}(s, t) + \text{possible terms with different } s\text{-channel poles.}$$

For $s = m_L^2$ and $\alpha(m_L^2) = L$,

$$A = \frac{\lambda}{\alpha'_A} \frac{1}{\Gamma(L)} \frac{2^L [\Gamma(L+1)]^2}{\Gamma(2L+1)} (2\alpha'_B k^2)^L \frac{P_L(\cos\theta)}{s - m_L^2} + \dots \quad (4.1)$$

Only particles on the leading trajectory are considered. The decay width of this particle L to $a + b$ is given in the narrow-resonance limit as

$$\begin{aligned}\Gamma_{L \rightarrow a+b} &= \xi_L \frac{k}{16\pi m_L^2} \lim_{s \rightarrow m_L^2} (s - m_L^2) \int_{-1}^1 d(\cos\theta) P_L(\cos\theta) A \\ &= \frac{\lambda}{16\pi} \xi_L (\alpha'_\rho)^{L-1} \left[\left(\frac{\alpha'_\rho}{\alpha'_A} \right) \left(\frac{\alpha'_B}{\alpha'_\rho} \right)^L \right] \frac{2^{L+1} L}{(2L+1)!!} \frac{k^{2L+1}}{m_L^2},\end{aligned}\quad (4.2)$$

where ξ_L is the isospin factor. We normalize the width in terms of α'_ρ . The factor in the square brackets,

$$\left(\frac{\alpha'_\rho}{\alpha'_A} \right) \left(\frac{\alpha'_B}{\alpha'_\rho} \right)^L, \quad (4.3)$$

gives rise to a symmetry breaking which can also be seen from the coupling constants. For the vector- and tensor-meson couplings one has

$$\begin{aligned}g_{Vab}^2 &= \frac{1}{2} \lambda \xi_1 \left(\frac{\alpha'_\rho}{\alpha'_A} \right) \left(\frac{\alpha'_B}{\alpha'_\rho} \right), \\ g_{Tab}^2 &= \frac{1}{4} \lambda \xi_2 \left(\frac{\alpha'_\rho}{\alpha'_A} \right) \left(\frac{\alpha'_B}{\alpha'_\rho} \right)^2 \alpha'_\rho.\end{aligned}$$

Equation (4.3) predicts a large symmetry-breaking effect for high-spin resonances on the ρ - f - ω - A_2 trajectory decaying into $K\bar{K}$ or $D\bar{D}$. A ready interpretation of this symmetry-breaking effect can be given in terms of quark diagrams. Suppose that the decaying particle L is made of quarks

$q_1\bar{q}_2$, particle a , $q_1\bar{q}_3$ and particle b , $q_3\bar{q}_2$. We shall call $q_1\bar{q}_2$ the initial quarks and $q_3\bar{q}_3$ the pair-created quarks. Then α'_A is the slope of the trajectory made of the initial quarks, and α'_B is that made of the pair-created quarks. (See Fig. 1.) Thus, α'_A is the slope of the trajectory on which the decaying particle lies and α'_B can only be α'_ρ , α'_ϕ , or α'_J . Therefore the first factor of Eq. (4.3), α'_ρ/α'_A , gives rise, in general, to an enhancement and the second factor, $(\alpha'_B/\alpha'_\rho)^L$, to a suppression. The latter can be understood intuitively as follows. The creation of a pair of heavy quarks from the vacuum is less probable than that of a pair of light quarks. This type of argument has been used in the literature in the discussion of couplings of $D\bar{D}$ (and $F\bar{F}$) to the ordinary vector mesons and to J/ψ and ψ' . The presence of the first factor $1/\alpha'_A$ is expected from the general formulas of the width of a resonance on a Regge trajectory.¹⁸

In order to determine all the trajectories and the widths given in Eq. (4.2), we use α'_ρ and the

FIG. 1. Quark-diagram interpretation of the symmetry-breaking effect of Eq. (4.3).

decay width $\Gamma_{\rho \rightarrow 2\pi}$ as inputs. The latter involves the least error of all the vector-meson decay widths and the former has been repeatedly determined in the spacelike region. We shall use $\alpha'_\rho \simeq 0.88 \text{ GeV}^{-2}$, which comes from the following information: (a) The ρ - f - ω - A_2 trajectory goes through $h(2.04)$ (Ref. 19) for $\alpha_\rho(m_h^2) = 4$. (b) A recent fit of the πN charge-exchange reaction²⁰ gives

$\alpha_\rho(0) = 0.48$, which leads to $\alpha'_\rho = 0.88 \text{ GeV}^{-2}$ when it is extrapolated to the timelike region and required to pass through the ρ .

Let us restrict ourselves in the following discussion to the equal-spacing rule, Eq. (3.2). In Table I, we list the resulting slope parameters and the predicted mass values together with the experimental masses if they exist. Input masses are underlined. The values of the slopes are close to those used by Igi.⁴ We note the following: (a) The resonance at $J=3$ on the K^*-K^{**} trajectory with the predicted mass 1.805 GeV can be identified with $K_N(1.8)$.²¹ (b) The predicted mass 3.677 on the α_J with $\alpha_J=3$ agrees well with that of $\psi'(3.684)$, since $\psi'(3.684)$ should be identified as the second daughter of $\alpha_J=3$ resonance on the α_J . (c) The F^* mass is predicted to be 2.14 GeV, which is higher than the prediction of 2.06 GeV in the charmonium model.²² We observe, however,

TABLE I. Predicted mass spectra and partial widths into two pseudoscalar mesons. (i) The underlined vector-meson masses, $\alpha'_\rho = 0.88 \text{ GeV}^{-2}$, and the $\rho \rightarrow 2\pi$ width are input. (ii) The decay, $D^{*0} \rightarrow D^0\pi$, is very close to the threshold; therefore, the calculated width is extremely sensitive to the masses of D^{*0} and D^0 used. See Ref. 22. (iii) $R_{ab} \equiv \alpha'_a/\alpha'_b$.

that the prediction of the charmonium model of the masses of D , D^* , and $\Lambda_c(2.25)$ are in general lower by 20–30 MeV compared with the experimental values.¹ (d) The mass-quantization rules, which are not part of our inputs, are satisfied reasonably well for the known pseudoscalar mesons. Using the ρ , K^* , D^* , F^* , and J/ψ trajectories in $\alpha_V(m_P^2) = \frac{1}{2}$, where m_P is the corresponding pseudoscalar mass, we obtain the first three relations from the Adler PCAC (partial conservation of axial-vector current) consistency condition but the last two cannot be derived this way. Solving these relations, we obtain $m_\pi = 0.147$, $m_K = 0.43$, $m_D = 1.82$, $m_F = 1.94$, and $m_{\eta_c} = 2.94$, all in units in GeV.

The various decay widths into two pseudoscalars are also given in Table I. Except for the $\rho \rightarrow 2\pi$ width, which is used as an input to fix λ^π , all the other widths listed are predictions. Experimental values of masses are used in the calculation if available. We also give the isospin factor ξ_L [see Eq. (4.2)] and the experimental widths. For the D^* , the width listed is for $D^{*0} \rightarrow D^0 \pi^0$, which is barely above the threshold and has been observed.²³ To indicate the symmetry-breaking effects, we also list the widths in terms of the slopes. All the predicted widths suffer an error of the order of 4%, mainly due to the ambiguity of the value of α'_ρ and the assumption of exact exchange degeneracy.

To conclude this section, a remark on $D^{*0} \rightarrow D^0 \pi^0$ is in order. It is very close to the threshold; therefore, the calculated width, strongly suppressed by the limited phase space, is sensitive to the mass values of D^{*0} and D^0 used. (We used the values given in Ref. 22.) Although the predicted width is of the order of keV,²³ the predicted coupling constant for $D^{*0} \bar{D}^0 \pi$ is larger than the SU(4)-symmetry value by the factor $(\alpha'_\rho/\alpha'_{D^*})^{1/2}$.

V. CONCLUSIONS

We emphasized that relations, such as the nonet mass formula, the equal-spacing rule, and the mass quantization rule, are related to the factorization requirement at the first daughter level in the case of the universal slope. Then we proposed that the factorization relation and equal-spacing rule, which relate the parameters of different trajectories, hold even when the trajectory slopes are different, and thereby we determined the parameters of all the leading meson trajectories in terms of the slope of the ρ trajectory. The predicted decay widths of vector mesons, tensor mesons, etc. into two pseudoscalars agree well with the data whenever a comparison can be made. The nondegenerate slopes improve the prediction of the corresponding degenerate slopes. This can be seen in, e.g., $\Gamma_{K^*(890) \rightarrow K\pi}$, which is independent of the ab-

solute value of α'_ρ . The predicted partial width agrees with the data within the experimental error, while the degenerate slopes, giving rise to exact SU(3)-[SU(4)-] symmetric couplings, predict a value which is three standard deviations too small in comparison with the data. Another interesting case is $D^{*0} \rightarrow D^0 \pi^0$ in which the predicted width is larger than the SU(4)-symmetric value by 30%. Note that the $D^* \bar{D} \pi$ coupling constant is dimensionless; therefore, it is not clear how to introduce a mass scale into the effective Lagrangian which can account for symmetry-breaking effects. In the present approach the scales are provided by the slope parameters whose ratios are determined by the factorization condition as well as the equal-spacing rule. An accurate measurement of the $D^{*0} \rightarrow D^0 \pi^0$, $K^{*}(1420) \rightarrow K\pi$, and $f \rightarrow K\bar{K}$ widths could serve as additional tests of the present scheme, in particular, as a test of the equal-spacing rules. A direct check of the equal-spacing rules can be achieved if the masses of recurrences of the various trajectories, as listed in Table I, are experimentally determined. Let us further notice that strong suppression will occur in the $K\bar{K}$ and $D\bar{D}$ mode of high-spin particles lying on the ρ - f - ω - A_2 trajectory, owing to the factors $(\alpha'_K/\alpha'_\rho)^L$ and $(\alpha'_{D^*}/\alpha'_\rho)^L$. An experimental check of these factors is possible for the former but remote for the latter.

There are other schemes beside ours which discuss nondegenerate slopes. One of them, proposed by Close *et al.*,²⁴ assumes the following relation between the slope α'_V of a leading trajectory and the lowest vector-meson mass on it, m_V : $\alpha'_V = \frac{3}{4} m_V^{-1}$. These slope parameters do not satisfy the factorization condition (3.1). Another scheme, proposed by Finkelstein and Tuan,⁴ in which $\alpha'_\rho \approx \alpha'_{D^*}$, etc. are assumed, leads to degenerate slopes when the factorization of the resonance residues is assumed.

As a concluding remark, beyond the present phenomenological level, a more precise formulation of the dual resonance model with nondegenerate slopes is necessary. In this formulation, it is necessary to define, among other things, the energy range outside of which the slopes become universal. This range was left unspecified in the present phenomenological treatment.

ACKNOWLEDGMENT

We would like to thank T. Walsh, M. Krammer, J. Körner, and T. C. Yang for reading the manuscript and helpful suggestions. M.K. thanks the Alexander von Humboldt Foundation for financial support. B.L.Y. takes the pleasure of thanking Professor H. Joos and Dr. T. Walsh for their kind hospitality at DESY and for financial support.

¹¹The actual values of slope parameters of the D^* and J/ψ trajectories are crucial in a certain model calculation of charmed-meson and -baryon production; see for example, C. Avilez, T. Kobayashi, and J. G. Körner, Phys. Lett. **66B**, 149 (1977); Report No. DESY 66B, 149 (1977); Phys. Rev. (to be published).

¹²This relation has been obtained by J. Pasupathy [Phys. Rev. Lett. **37**, 1336 (1976)] and by Igi (Ref. 6) by means of factorization of the Regge expansion in the t vari-

able of, say, Eq. (2.1) in the medium-energy region.

Such a procedure, which requires the validity of asymptotic expansion of Γ functions, leads to an exponential increase (Ref. 7) of the $\pi K \rightarrow \pi K$ amplitude at fixed angle θ , for $\cos\theta < 1 - 2\alpha'_K/\alpha'_\rho$. We do not regard this exponential increase as a reasonable behavior to occur in the medium energy region, although it disappears eventually as $t \rightarrow \infty$. Our derivation of Eq. (2.8) is carried out in the resonance region and does not suffer from this difficulty.

¹³The second and younger daughters are not factorizable even in the case of degenerate slope. See Freund, Ref. 10.

¹⁴We discard another solution, e.g.

$$\alpha'_{K^*} = \alpha'_\rho \frac{m_{K^*}^2}{m_\phi^2} [1 - (1 - m_\rho^2 m_\phi^2 / m_{K^*}^4)^{1/2}],$$

etc., on the ground that it gives $\alpha'_{K^*} = 0$ when the nonet mass relation $m_\rho^2 + m_\phi^2 = 2m_{K^*}^2$ is exact.

¹⁵These relations are derived from the quantization rules with universal slope; see McKay and Young, Ref. 3.

¹⁶Higher-order symmetry-breaking effects in the Gell-Mann-Okubo mass formula have been considered by S. Okubo, Phys. Lett. **4**, 74 (1963), and M. A. Rashid and I. I. Yamanaka, Phys. Rev. **131**, 2797 (1963).

¹⁷The values of m_ρ and m_{K^*} used here are the average of the charged and neutral masses given in Particle Data Group, Rev. Mod. Phys. **48**, S1 (1976).

²³G. Goldhaber, Report No. LBL-5534 (unpublished). In the calculation of $\Gamma_{D^*0 \rightarrow D^0 \pi^0}$ we used the mass values quoted in this article: $m_{D^0} = 1.8665$, $m_{D^*0} = 2.0067$. In all the other width calculations involving D and π we used $m_D = 1.87$ and $m_\pi = 0.137$. This article also gives $\Gamma(D^*0 \rightarrow D^0 \gamma) / \Gamma(D^*0 \rightarrow D^0 \pi^0) = 0.54 \sim 0.82$, which indicated that the experimental width of $D^*0 \rightarrow D^0 \pi$ is probably of the order of keV.
