# How large a cross section?

- To be observable on astrophysical scales, self-interaction cross sections have to be large, typically

$$\sigma / m_\chi \sim 1 \text{ cm}^2/\text{g} \sim 2 \text{ barns}/\text{GeV}$$

- The nucleon nucleon scattering cross section  $\sim 20$  barns at low energies
- The typical cross section of a WIMP is 20 orders of magnitude smaller!
  
- **Potential impact:** Evidence for DM self-interactions on astrophysical scales would rule out many popular models for DM, such as supersymmetric WIMPs, gravitinos, axions...

# The particle physics perspective

- Assume  $2 \rightarrow 2$  elastic scattering (inelastic possible for multi-component DM with small mass splitting, collective effects possible if DM a plasma)

- The scattering cross-section can have an **angular** and a **velocity** dependence
- For single scatter momentum transfer completely fixed by the scattering angle.
- Effective momentum transfer is given by

$$\sigma_T = 2\pi \int_{-1}^1 \frac{d\sigma}{d\Omega} (1 - |\cos \theta|) d \cos \theta$$

- This is the quantity typically studied (and implemented in N-body simulations)

# The particle physics perspective

- However, this is not all that matters...
- Can be obtained with **rare scatters and large momentum transfer** (e.g. isotropic scattering) or **frequent scatters with small momentum transfer** (e.g. long range interactions)
- The different underlying physics can result in different observable effects

# A smoking gun observable

- Smoking gun signal? Separation between dark matter halo and stars of a galaxy falling into a galaxy cluster

# Smoking gun?

- Smoking gun signal? Separation between dark matter halo and stars of a galaxy falling into a galaxy cluster

Observed offset:  $1.62 \pm 0.48 \text{ kpc}$

Reanalysis from 2017 – offset gone :-)

# More generally: Distinguishing different types of SIDM

Kahlhoefer et al, 1504.06576

- **Effective drag force:** the DM subhalo retains its shape, while the distribution of stars are both shifted and deformed.
- **Contact interactions:** the DM subhalo is deformed due to the scattered DM particles leaving the subhalo in the backward direction.
- Potentially distinguishable (but very tough)!
- At this point no indication either way...what about the velocity dependence?

# What about the velocity dependence?

- Different astrophysical systems have different typical velocities!

# Velocity dependent self-interactions

- Idea: Relate core size of different systems to SIDM cross section
- Simple analytical model to do this fit
- DM self-interactions seem to depend on the typical relative velocity of DM particles.
- But taken with a grain of salt (baryonic effects again...)

# SIDM model building

## 1) Very light dark matter

- Large DM number densities lead to large self-interaction rates  $\sigma / m_\chi$
- Relic density set e.g. by direct annihilation into SM states

Chu, Garcia-Cely, Hambye,  
1609.00399

  - Relic density set by direct annihilation into pairs of mediators
- Feng, Kaplinghat, Yu: arXiv:0905.3039; Buckley & Fox: arXiv:0911.3898; Loeb & Weiner: arXiv:1011.6374

Velocity dependent scatterings

# Velocity dependent self-interactions

- Idea: Relate core size of different systems to SIDM cross section
- DM self-interactions seem to depend on the typical relative velocity of DM particles.
- Simplest realisation  
→ light mediator!

Loeb & Weiner: arXiv:1011.6374

- Scales as  $1/(q^2 + m_{\text{med}}^2)^2$ 
  - Scattering for small momentum transfer ( $q < m_{\text{med}}$ ) proportional to  $1/m_{\text{med}}^4$
  - Scattering for large momentum transfer ( $q > m_{\text{med}}$ ) proportional to  $1/q^4$

# A new light mediator

- > The relic abundance is typically set by annihilations into pairs of mediators (so-called dark sector freeze-out):

Fix dark sector coupling via relic abundance

# A new light mediator

- The relic abundance is typically set by annihilations into pairs of mediators (so-called dark sector freeze-out):

Fix dark sector coupling via relic abundance

- To avoid overclosing the Universe, the mediator should ultimately disappear, so its couplings to SM states cannot be arbitrarily small – many constraints

# Enhancement of DM self-interactions

- DM self-interactions are enhanced also by non-perturbative effects due to multiple mediator exchange.
- Scalar and vector mediators particularly interesting

Dark matter with relic density ( $s$ -wave)

strong velocity dependence

weak velocity dependence

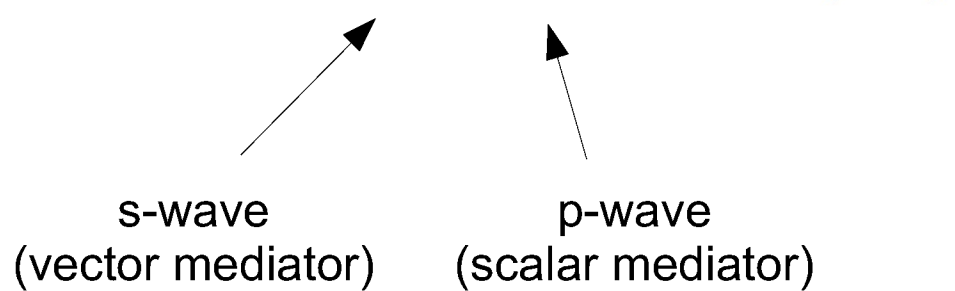

Tulin et al., arXiv:1302.3898

# DM annihilations – s-wave vs. p-wave

- > At freeze out dark matter is semi-relativistic, in the later Universe it is non-relativistic.
- > Annihilation cross section can depend on relative velocity
- > Make expansion in velocity

$$\sigma v_{\text{rel}} = \sigma_0 + \sigma_1 v_{\text{rel}}^2 + \mathcal{O}(v_{\text{rel}}^4)$$

s-wave (vector mediator)      p-wave (scalar mediator)

- > Both terms contribute at freeze-out. Later p-wave is very suppressed...

# Enhancement of DM annihilations

- Significant non-perturbative corrections to the tree-level annihilation rate (Sommerfeld enhancement).
- Effects small during freeze-out, but increase with decreasing DM velocity as  $1/v$ .
- Saturates when  $v \sim m/M$

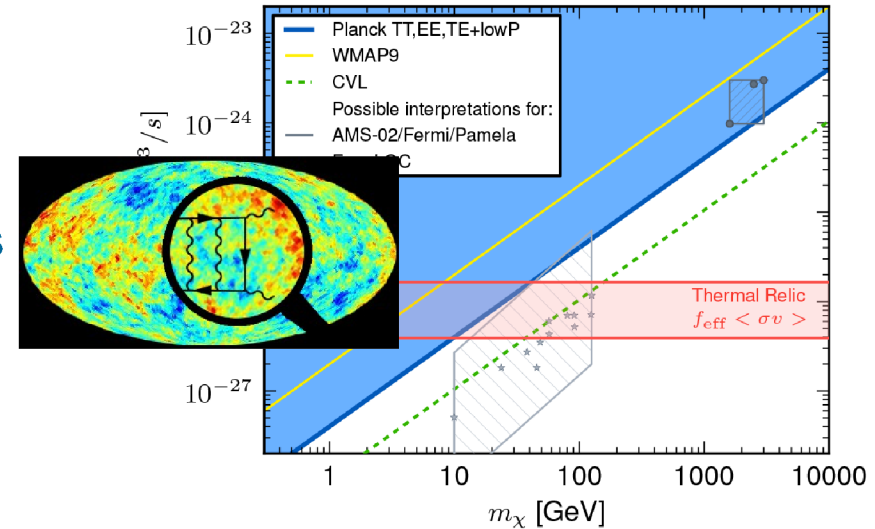

During recombination dark matter particles move at walking speed.

# Constraints on DM self-interactions

- DM annihilations during recombination, followed by mediator decays into SM particles, inject energetic electrons and photons into the plasma.
- These energetic particles can re-ionize neutral atoms and thereby spoil the excellent agreement between predictions and measurements of the CMB

→ very strong constraints for s-wave annihilation

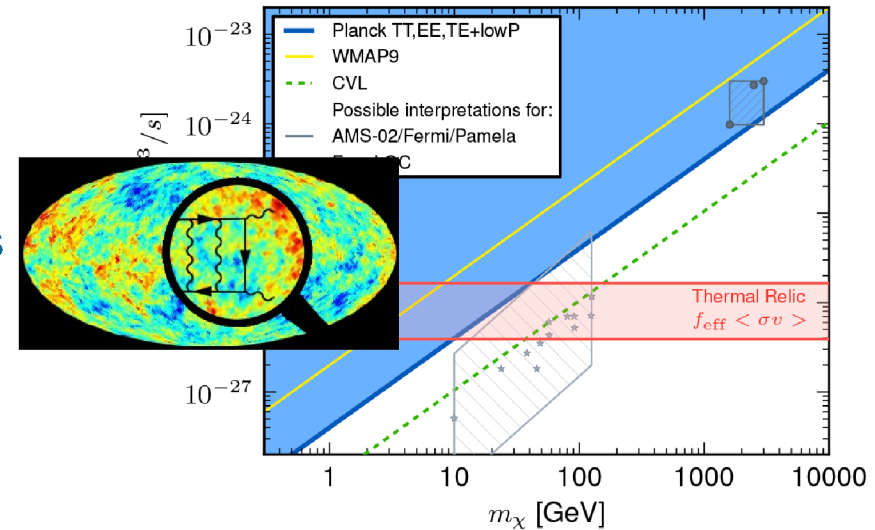

# Constraints on DM self-interactions

- DM annihilations during recombination, followed by mediator decays into SM particles, inject energetic electrons and photons into the plasma.
- These energetic particles can re-ionize neutral atoms and thereby spoil the excellent agreement between predictions and measurements of the CMB

→ very strong constraints for s-wave annihilation

- DM-nucleon scattering cross section also scales as  $1/(q^2 + m_{\text{med}}^2)^2$
- strongly enhanced for light mediators!

# Vector mediators

- Example: A new gauge boson from a spontaneously broken U(1)' gauge group that mixes with the neutral gauge bosons of the Standard Model.

$$\mathcal{L} \supset -g_\chi^V \phi^\mu \bar{\chi} \gamma_\mu \chi - \frac{1}{2} \sin \epsilon B_{\mu\nu} \phi^{\mu\nu} - \delta m^2 \phi^\mu Z_\mu$$

Kinetic mixing:  
Mediator obtains photon-like couplings

Mass mixing:  
Mediator obtains Z-like couplings

## ➤ Main difference:

- A gauge boson with kinetic mixing is effectively stable below the electron threshold.
- Mass mixing induces sizable decay rates into neutrinos

# Constraints on vector mediators

- For vector mediators, DM annihilation proceeds via s-wave:
  - Large Sommerfeld enhancement for small velocities
  - $g_x$  fixed by relic density – essentially independent of coupling to SM

Bringmann et al., arXiv:1612.00845

Bringmann et al., arXiv:1612.00845

# Constraints on vector mediators

- Only assumption: The two sectors have the same temperature during freeze out.
- Kinetic mixing often required to be too small to bring into thermal equilibrium due to DD constraints
- But even for different temperatures in the two sectors there are very strong constraints.

# Scalar mediators

- Example: A real scalar singlet that obtains a vacuum expectation value and mixes with the SM Higgs boson.
  - This mixing induces Yukawa-like couplings to SM fermions consistent with minimal flavour violation:
- $$\mathcal{L} = \mathcal{L}_{\text{SM}} - \frac{g_y m_f}{v} \phi \bar{f} f - \frac{1}{2} \kappa \phi \bar{\chi} \chi$$
- Branching ratios in the GeV region are difficult to calculate due to hadronic resonances
  - We are interested in smaller masses where uncertainties are small

# Constraints on scalar mediators

- For fermionic DM and scalar mediators annihilation proceeds via p-wave
- No constraints from indirect detection or the CMB.
- Direct detection constraints are very strong for scalar mediators.
- Lifetime rather long due to Yukawa suppression
- Naive BBN bound:  $\tau < 1$  s
- How does this depend on  $y_{SM}$ ?

1704.02149

# Constraints on scalar mediators

- For fermionic DM and scalar mediators annihilation proceeds via p-wave
- No constraints from indirect detection or the CMB.
- Direct detection constraints are very strong for scalar mediators.
- Lifetime rather long due to Yukawa suppression
- Naive BBN bound:  $\tau < 1$  s
- How does this depend on  $y_{SM}$ ?

1704.02149

# Constraints on scalar mediators

- In a different plane, fixing the cross section at dwarf scales

- Requires dedicated BBN study (ongoing)

# Pseudoscalar mediators

$$\mathcal{L}_{\text{DM}} = i g_\chi A \bar{\chi} \gamma^5 \chi$$

$$\mathcal{L}_{\text{SM}}^{(Y)} = i g_Y \sum_{f=q,\ell} \frac{\sqrt{2} m_f}{v} A \bar{f} \gamma^5 f$$

- In the non-relativistic limit, scattering via the exchange of pseudoscalar mediators is strongly suppressed by powers of the momentum transfer.
- Direct detection constraints are therefore effectively absent
- The same effect suppresses DM self-scattering
- Strongest bounds come from direct searches for light pseudoscalars.

Dolan et al., arXiv:1412.5174

# Ways out for light mediators

- There are a number of ways to evade the various constraints
  - Mixed scalar/pseudoscalar couplings (CP violation)  
Kahlhoefer et al; 1704.02149
  - Inert decays of the mediator, for example into (sterile) neutrinos
  - No thermalization (DM production via the freeze-in mechanism)  
Bernal et al., arXiv:1510.08063
  - Stable mediator (which largely annihilates away)  
Ma, 1704.04666
  - Suppressed couplings to quarks (to evade direct detection constraints)
  - Small mass splitting (inelastic scattering)  
Blennow et al., 1612.06681
- Exciting phenomenology and interesting model-building challenges!

# Idea: A mixed mediator (CP violation)

$$\mathcal{L}_{\text{DM}} \supset y_\psi \cos \delta_\psi \bar{\psi}\psi\phi + y_\psi \sin \delta_\psi i\bar{\psi}\gamma^5\psi\phi$$

- For  $\delta_\psi \sim 0$  (like a scalar) DM self-interactions can be large.
- For  $\delta_{\text{SM}} \sim \pi/2$  (like a pseudoscalar) direct detection constraints are strongly suppressed.
- Large allowed parameter space!
- Constraints on the CP-violating phase  $\delta_{\text{SM}}$  (e.g. from electron EDMs) can be satisfied even for very light mediators as long as  $y_{\text{SM}}$  is sufficiently small ( $y_{\text{SM}} \ll 10^{-2}$ ).

# The return of CMB constraints

- Central problem: The fact that annihilation can only proceed via p-wave was a consequence of CP conservation.
- As soon as  $\delta_\psi$  is not exactly zero, s-wave annihilation is again possible and will receive large Sommerfeld enhancement.

# Inert decays of the mediator

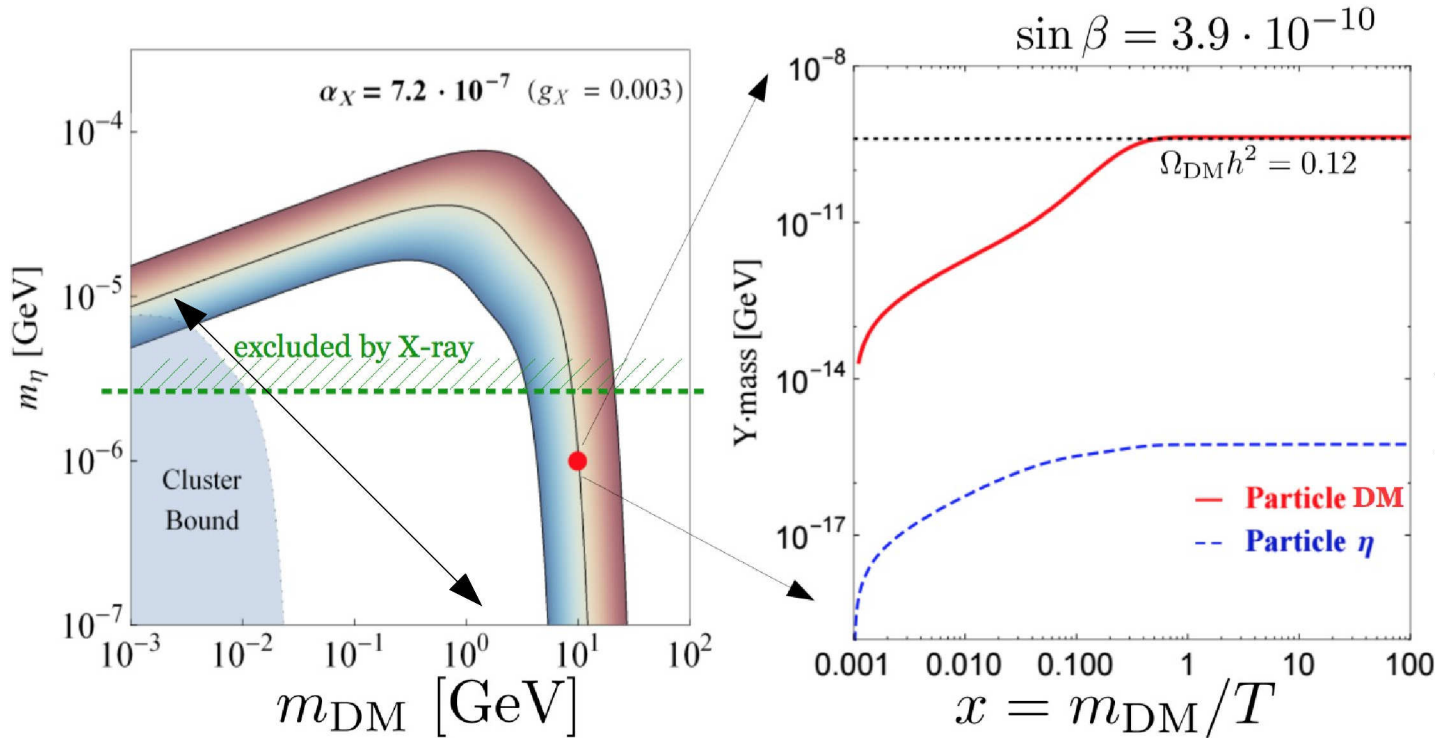

- Assume vector mediator couples mainly to sterile neutrinos
- Extra energy contribution which affects the expansion rate  $H$
- Changes predictions for BBN

# Freeze in

- Thermal production via freeze in
- General analysis of parameter space ('phase diagram')

Chu, Hambye, Tytgat;  
1112.0493

A lot less mediators!

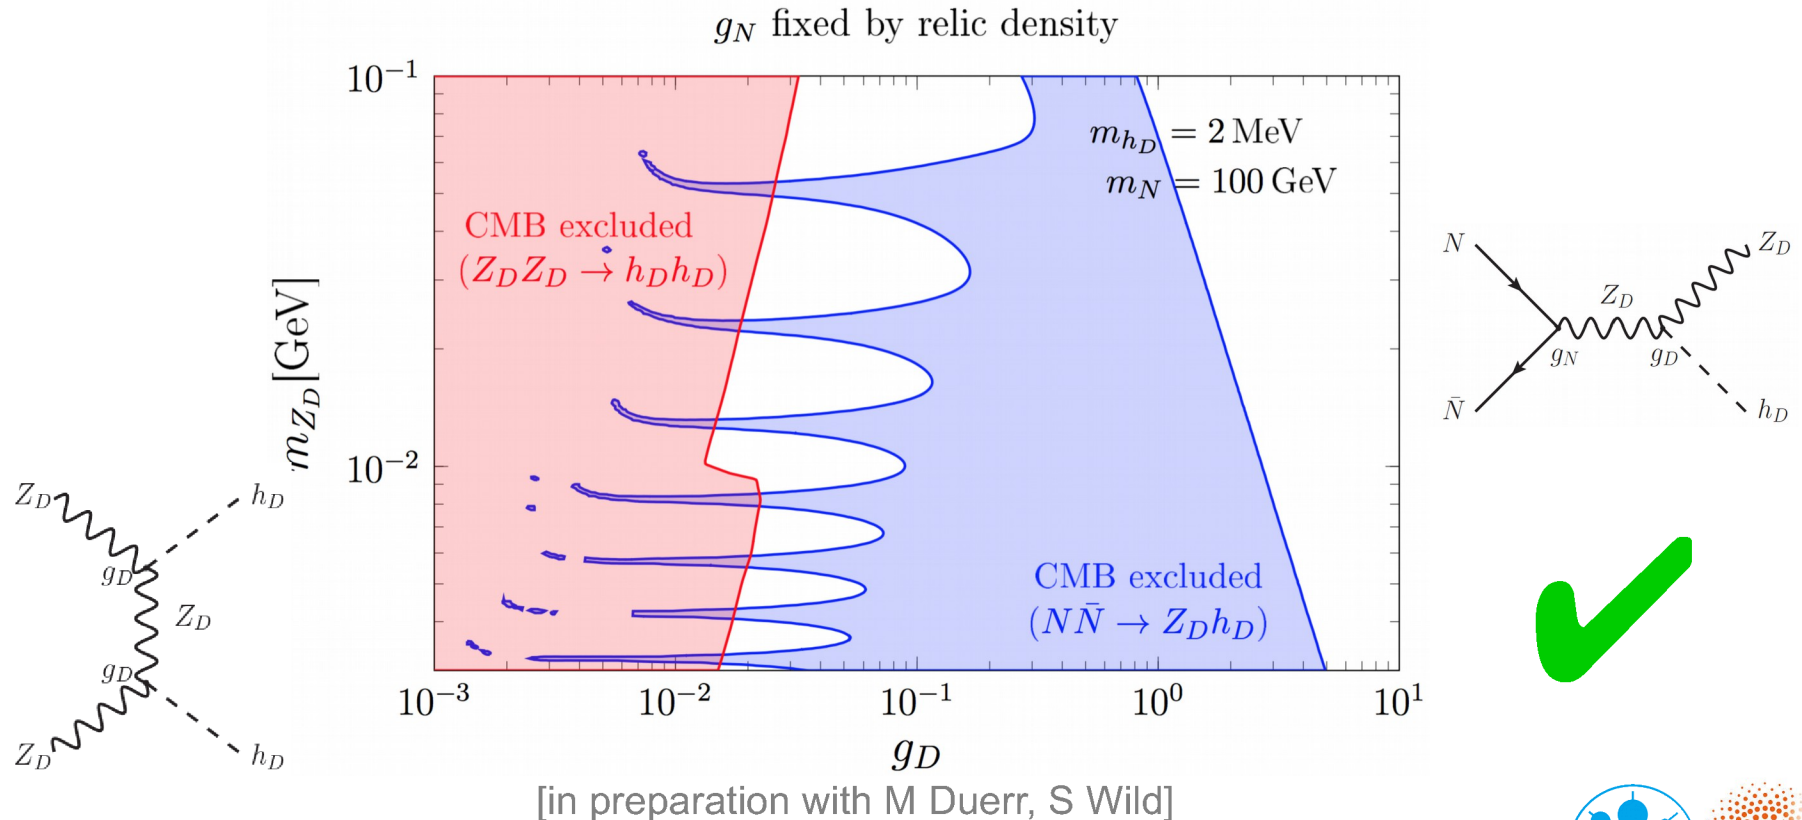

[Bernal, Chu, Garcia-Cely, Hambye & Zaldivar, 1510.08063]

# Stable mediator

Ma, 1704.04666

- Assume vector mediator  $Z_D$  is stable
- Introduce dark Higgs  $h_D$  to give mass, decays via mixing with SM Higgs
- Still constraints from CMB due to Higgs decays, but not ruled out

# Summary

- Self interacting dark matter could solve some problems of the collisionless cold dark matter paradigm and can arise naturally in more complex dark sectors
- Orthogonal handle on properties of DM: We can potentially study the dark sector even if DM has highly suppressed couplings to Standard Model particles.
- Can potentially distinguish effective drag forces (from frequent self-interactions) and rare self-interactions
- Some preference for a velocity dependence of the cross section.
- The simplest possibilities (scalar or vector mediator with no additional new states) are in strong tension with direct and indirect detection experiments.
- A couple of ways around this conclusion, interesting model building
- Huge possible impact, ruling out WIMPs, axions, gravitinos,...

# Thank you!
