Measurements of differential cross sections of top quark pair production as a function of kinematic event variables in proton-proton collisions at $\sqrt{s} = 13$ TeV

The CMS Collaboration*

Abstract

Measurements of differential $t\bar{t}$ production cross sections are presented in the single-lepton decay channel, as a function of a number of kinematic event variables. The measurements are performed with proton-proton collision data at $\sqrt{s} = 13$ TeV, collected by the CMS experiment at the LHC during 2016, with an integrated luminosity of 35.9 fb^{-1} . The data are compared to a variety of state-of-the-art leading-order and next-to-leading-order $t\bar{t}$ simulations.

Submitted to the Journal of High Energy Physics

1 Introduction

In 2016 the CERN LHC collided protons at $\sqrt{s} = 13$ TeV, resulting in a data set recorded by the CMS experiment [1], with an integrated luminosity of 35.9 fb^{-1} . Approximately 30 million top quark-antiquark pairs ($t\bar{t}$) are present in this data set, which allows detailed studies of the production properties of $t\bar{t}$ events to be performed.

Measurements of kinematic distributions in $t\bar{t}$ events are important for verifying current theoretical models of $t\bar{t}$ production and decay. As $t\bar{t}$ production and top quark decay can be a significant source of background events in many searches for physics beyond the standard model, for example in searches for supersymmetric models with top-quark-like signatures, it is important that $t\bar{t}$ production be well understood and modeled. In addition to physics beyond the standard model, a good understanding of $t\bar{t}$ production is necessary for measurements of rare standard model processes, such as $t\bar{t}$ production in association with a W, Z, or Higgs boson.

In this paper, we present measurements of differential $t\bar{t}$ production cross sections, as a function of kinematic event variables that do not require the reconstruction of the $t\bar{t}$ system. Events are considered when the final state includes exactly one isolated lepton ($\ell = e$ or μ) with large transverse momentum p_T and at least four jets, of which at least two are tagged as originating from a bottom (b) quark. The kinematic event variables are the jet multiplicity (N_{jets}), the scalar sum of the jet p_T (H_T), the scalar sum of the p_T of all particles (S_T), the transverse momentum imbalance (p_T^{miss}), the magnitude of the p_T of the leptonically decaying W boson (p_T^W), and the magnitudes of the p_T and pseudorapidity of the lepton (p_T^ℓ and $|\eta^\ell|$).

The measurements of the differential $t\bar{t}$ production cross sections are presented at particle level, i.e. with respect to generated “stable” particles (with a mean lifetime longer than 30 ps), in a phase space that closely resembles that accessible by the CMS detector (the visible phase space). This avoids the influence of large theoretical uncertainties that would be introduced by extrapolating the measurements to a larger phase space, or by presenting the measurements at parton level.

Several measurements of the differential $t\bar{t}$ production cross sections as a function of the properties of the $t\bar{t}$ system and of the jet activity in $t\bar{t}$ events have been performed at the LHC, at 7 and 8 TeV [2–6], and 13 TeV [7–10]. Measurements with respect to kinematic event variables in $t\bar{t}$ events have been performed with the CMS detector at 7 and 8 TeV [11].

2 The CMS detector

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field strength of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter, each composed of a barrel and two endcap sections. Forward calorimeters extend the η coverage provided by the barrel and endcap detectors. Muons are measured in gas-ionization detectors embedded in the steel flux-return yoke outside the solenoid. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [1].

Events of interest are selected using a two-tiered trigger system [12]. The first level, composed of custom hardware processors, uses information from the calorimeters and muon detectors to select events at a rate of around 100 kHz within a time interval of less than 4 μs . The second level, known as the high-level trigger (HLT), consists of a farm of processors running a version of the full event reconstruction software optimized for fast processing, and reduces the event

rate to around 1 kHz before data storage.

3 Signal sample and background simulation

Two independent $t\bar{t}$ samples are simulated with the POWHEG (v2) generator [13–16], which utilizes next-to-leading-order (NLO) matrix-element calculations. One sample uses PYTHIA (v8.212) [17, 18] with the CUETP8M2T4 tune [19] for the simulation of the parton shower and hadronization. The second has parton showering and hadronization performed by HERWIG++ (2.7.1) [20] using the tune EE5C [21].

Two additional independent simulated $t\bar{t}$ samples are produced with the MG5_aMC@NLO (v2.2.2) generator [22]. In the first, MG5_aMC@NLO is used to generate events at leading-order (LO) accuracy with up to three additional partons, and PYTHIA is employed with the CUETP8M1 tune [23] for parton showering and hadronization. The MLM jet-parton matching algorithm [24] is used in this sample, referred to as MG5_aMC@NLO-LO. In the second, MG5_aMC@NLO simulates events to NLO accuracy with up to two additional partons, where parton showering and hadronization are performed using PYTHIA with the CUETP8M2T4 tune. The FxFx jet-parton matching algorithm [25] is used, and this sample is referred to as MG5_aMC@NLO-NLO. It is important to compare multiple $t\bar{t}$ generators in order to find the current most suitable description of top quark production and decay, and to identify any discrepancies in the models.

In all simulated $t\bar{t}$ samples, the top quark mass is set to 172.5 GeV. The NNPDF30_nlo_as_0118 parton distribution function (PDF) set is used for the NLO samples while the NNPDF30_lo_as_0130 set is used for the LO samples [26]. When comparing with reconstructed data, a cross section of 832_{-29}^{+20} (scale) ± 35 (PDF + α_s) pb is used to normalize the $t\bar{t}$ samples, where α_s is the strong coupling constant. This $t\bar{t}$ cross section is calculated to next-to-next-to-leading-order (NNLO) accuracy in quantum chromodynamics (QCD) including resummation of next-to-next-to-leading logarithmic soft-gluon terms with TOP++ (v2.0) [27–33]. The scale uncertainty in this $t\bar{t}$ cross section comes from the independent variation of the factorization and renormalization scales.

The dominant background processes to $t\bar{t}$ production, i.e. the production of single top quarks and the production of vector bosons in association with jets, are also simulated. Single top quark processes are generated with POWHEG interfaced with PYTHIA, and are normalized to cross sections that are calculated to NLO precision [34, 35]. Separate samples are generated for t - and s -channel production [36, 37], and for the production of single top quarks in association with a W boson [38]. Samples of W and Z boson production with leptonic final states, in association with jets (V+jets), are generated with MG5_aMC@NLO-LO. Separate samples are generated with exactly one, two, three, and four additional jets to ensure a large sample of events that are likely to mimic the signature of $t\bar{t}$ production. These samples are normalized to their NNLO cross sections [39].

In addition, QCD multijet events are generated with PYTHIA for matrix-element calculations, parton shower simulation, and hadronization. To obtain a large sample of QCD multijet events that are likely to mimic the signature of $t\bar{t}$ production in the single-lepton decay channel, only events with large electromagnetic activity or containing a muon are generated. These samples are normalized to their LO cross sections and are used to create transfer factors from a control region to the signal region for a QCD background estimate based on data in the control region. The CMS detector response for all simulated samples is modelled using GEANT4 [40].

4 Event reconstruction and selection

Parallel selection paths are defined to target $t\bar{t}$ events that decay to final states containing an electron (e+jets) or a muon (μ +jets). The HLT in the e+jets channel requires at least one isolated electron candidate with $p_T > 32 \text{ GeV}$ and $|\eta| < 2.1$. The corresponding requirements in the μ +jets channel are at least one isolated muon candidate with $p_T > 24 \text{ GeV}$ and $|\eta| < 2.4$.

Offline reconstruction and selection uses the particle-flow (PF) algorithm [41] to reconstruct and identify each individual particle with an optimized combination of information from the subdetectors of CMS. In the e+jets channel, electron candidates are required to satisfy $p_T > 34 \text{ GeV}$ and $|\eta| < 2.1$. Electron candidates whose energy deposition in the ECAL is in the transition region between the barrel and endcap regions of the ECAL are not considered due to less efficient electron reconstruction. Electron candidates must also satisfy several identification criteria [42] to suppress the rate of jets and converted photons that are identified incorrectly as electron candidates. In addition, electron candidates must be isolated. To calculate the isolation, a cone of size $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} = 0.3$ is constructed around the electron direction, where ϕ is the azimuthal angle. The sum of the p_T of all PF candidates within this cone is calculated, excluding the lepton candidate and is corrected for the effects of additional proton-proton collisions within the same or nearby bunch crossings. The relative isolation variable I_{rel} is defined as the ratio of this sum to the electron p_T , and is required to be less than 6%.

In the μ +jets channel, muon candidates are required to satisfy $p_T > 26 \text{ GeV}$ and $|\eta| < 2.4$. Similarly to the electron candidates, muon candidates must satisfy additional identification criteria [43]. Muon candidates must be isolated, satisfying $I_{\text{rel}} < 15\%$ where I_{rel} is defined as for electrons, but with a cone of size $\Delta R = 0.4$.

For both electron and muon candidates, the lepton must be associated with the primary interaction vertex of the event. The primary interaction vertex is defined as the reconstructed vertex associated with the largest sum of p_T^2 from physics objects that have been defined using information from the tracking detector, including jets, the associated missing transverse momentum, which was taken as the negative vector sum of the p_T of those jets, and charged leptons.

The trigger, reconstruction and identification efficiencies for both electrons and muons are measured in data, and corrected in simulation to match those seen in data. The efficiencies are calculated using the tag-and-probe method [44] from events containing a Z boson. The total lepton correction factors are between 0.95 and 1.

Jets are clustered from PF candidates with the anti- k_T algorithm [45] implemented in the FAST-JET package [46], with a distance parameter of 0.4. The jet momentum is determined as the vector sum of the p_T of all PF candidates in the jet. A correction is applied to jet energies to take into account the contribution from additional proton-proton interactions using the charged hadron subtraction method [47]. The measured energy of each jet is corrected for known variations in the jet energy response as a function of the measured jet η and p_T . Jets are required to satisfy $p_T > 30 \text{ GeV}$ and $|\eta| < 2.4$. Jets closer than $\Delta R = 0.4$ to identified isolated leptons are removed, as they are likely to have originated from the lepton itself.

The combined secondary vertex algorithm [48, 49] is used to identify jets originating from a b quark. The threshold of the algorithm is chosen such that the identification efficiency (in simulation) of genuine b quark jets is $\approx 70\%$, and the probability to mistag a light quark or gluon jet is $\approx 1\%$. The identification efficiency of b quark jets in simulation is corrected to match that seen in data.

The distribution of the number of additional proton-proton interactions in simulation is corrected to match data. Events must contain exactly one high- p_T , isolated electron or muon. Events are vetoed if they contain an additional isolated lepton candidate with $p_T > 15$ GeV and $|\eta| < 2.4$. Events must also contain at least four jets, at least two of which are required to be identified as originating from a b quark.

5 Cross section measurement

As stated in Section 1, the differential $t\bar{t}$ production cross sections are measured as a function of the kinematic event variables: N_{jets} , H_T , S_T , p_T^{miss} , p_T^W , p_T^ℓ and $|\eta^\ell|$. The N_{jets} variable is the total number of jets in the event with $p_T > 30$ GeV and $|\eta| < 2.4$. The variable H_T is the scalar sum of the p_T of these jets. The quantity p_T^{miss} is defined as the magnitude of \vec{p}_T^{miss} , the transverse projection of the negative vector sum of the momenta of all reconstructed PF candidates in an event. The p_T^ℓ and $|\eta^\ell|$ variables are magnitudes of the transverse momentum and the pseudorapidity of the lepton in the event, respectively. The variable S_T is the sum of H_T , p_T^{miss} , and p_T^ℓ . The variable p_T^W is the magnitude of the transverse momentum of the leptonically decaying W boson, which is constructed from \vec{p}_T^ℓ and \vec{p}_T^{miss} .

The distributions of these variables measured in data are shown in Figs. 1 and 2, and are compared to the sum of signal and background events from simulation. A total of 662 381 events are measured in data, of which 92.1% are predicted from the POWHEG+PYTHIA simulation to be $t\bar{t}$ events. Single top quark production and V+jets production contribute 4.4% and 2.1% to the total number of events, respectively, as estimated from simulation. The component of multijet QCD events is estimated from control regions in the data, and comprises approximately 1.4% of the total number of events. The control regions are designed to obtain data samples that are enriched in QCD multijet events that are kinematically similar to the signal region, but with little contamination from $t\bar{t}$, single top quark, and V+jets events. In the e+jets channel, the control region is obtained by inverting the isolation criterion on electron candidates. In the μ +jets channel, the control region is obtained by requiring muon candidates to satisfy $0.15 < I_{\text{rel}} < 0.30$. In the control regions for both channels, the number of b-tagged jets is also required to be exactly zero. The contribution of $t\bar{t}$, single top quark and V+jets events to the control regions (≈ 15 –20%) is estimated from simulation with all corrections and subtracted from the data. The ratio of the number of multijet QCD events in the control region to that in the signal region (the transfer factor), both predicted from simulation, is then used to scale the normalization of the data control region to obtain the multijet QCD estimate in the signal region. Other sources of background are negligible, and are not considered in this measurement. The level of agreement between the total event count of data and simulation, within 0.2%, indicates that the total cross section is compatible to that stated in Section 3.

Previous measurements [2–8] report that the top quark p_T spectrum in data is softer than that predicted by NLO simulation, the effect of which can be seen in some of the distributions in Figs. 1 and 2. Including NNLO corrections in the simulation improves the agreement with the top quark p_T spectrum in data [50].

5.1 Particle level and visible phase space definitions

The results are presented at particle level, i.e. with respect to stable particles generated in the physics modeling before detector simulation. The generator-level definitions for the particles and visible phase space are based on the RIVET framework [51], following the prescriptions adopted in Ref. [52]. Generated electrons and muons not originating from a hadron or a quark are used to define electrons and muons at particle level. Photons that are near the lepton are

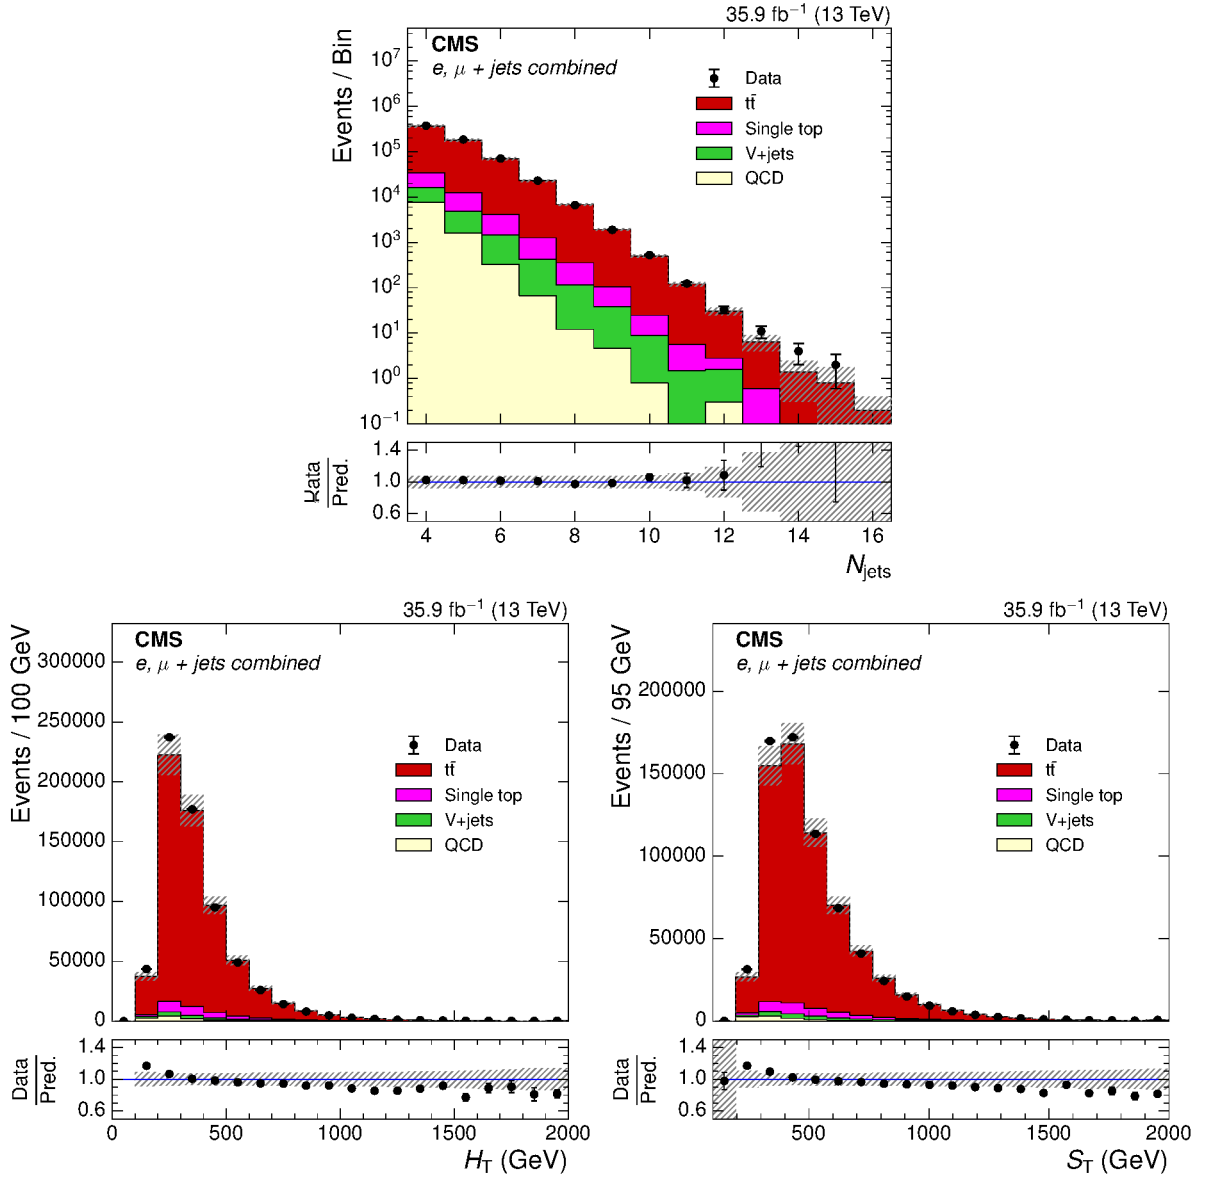

Figure 1: The distributions of N_{jets} , H_T and S_T after full event selection. The $t\bar{t}$ simulation is normalized to the NNLO prediction. The ratio of the number of events in data to that in simulation is shown below each of the distributions, with the statistical uncertainty in the data shown by the vertical uncertainty bars. The statistical uncertainty in the number of simulation events and the uncertainties in the modeling in simulation are shown by the hatched band.

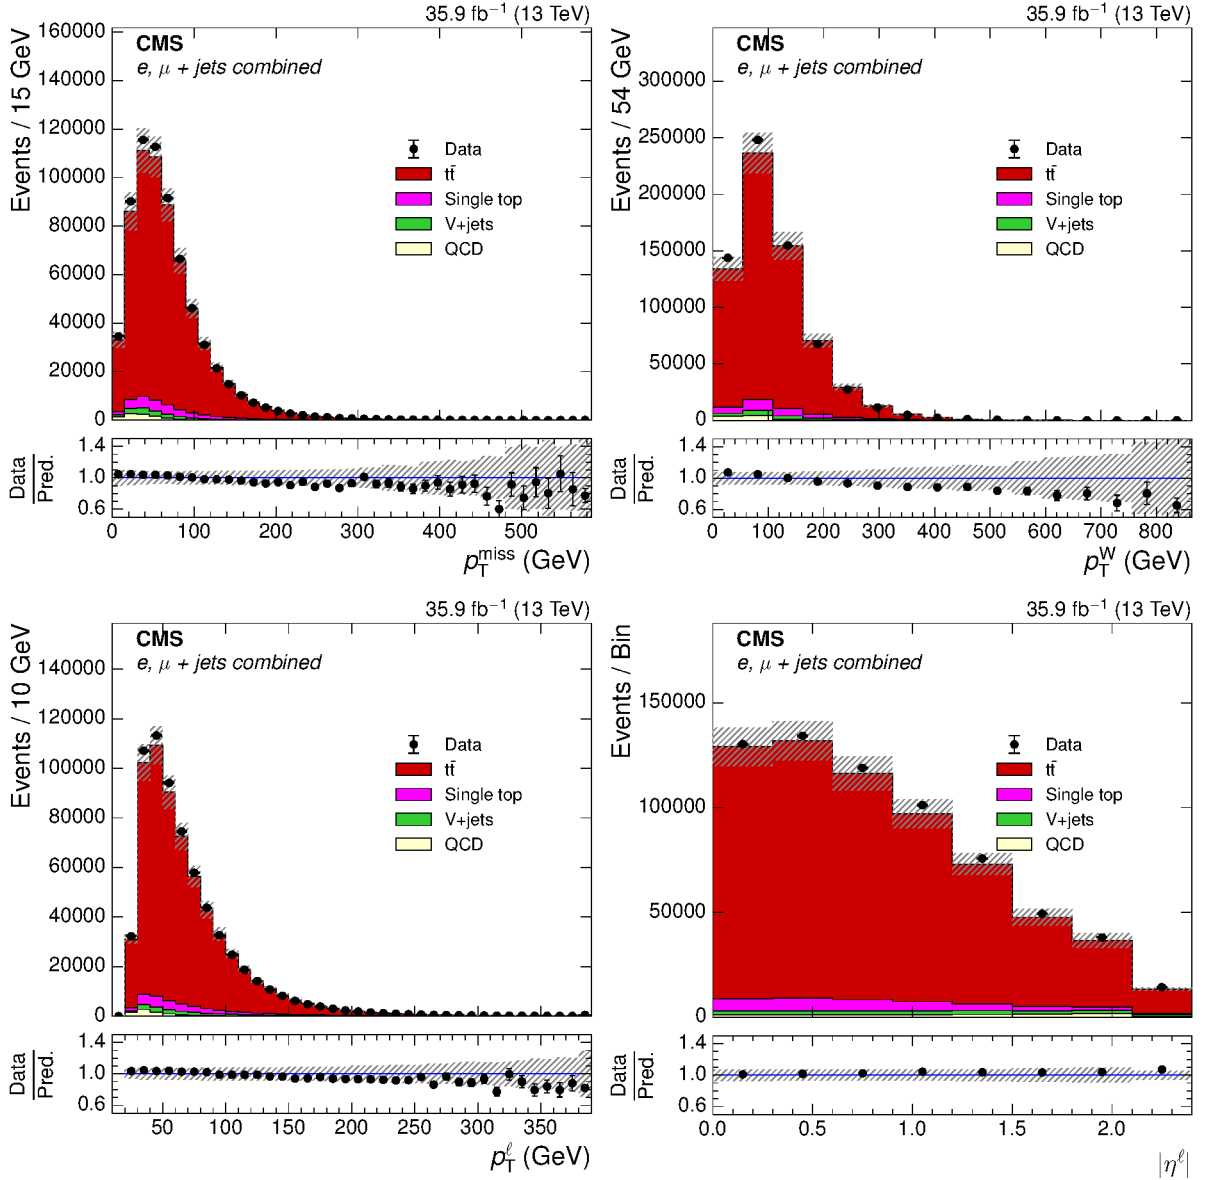

Figure 2: The distributions of p_T^{miss} , p_T^W , p_T^l and $|\eta^l|$ after full event selection. The $t\bar{t}$ simulation is normalized to the NNLO prediction. The ratio of the number of events in data to that in simulation is shown below each of the distributions, with the statistical uncertainty in the data shown by the vertical uncertainty bars. The statistical uncertainty in the number of simulation events and the uncertainties in modeling in simulation are shown by the hatched band.

assumed to have radiated from it, and are clustered together with the anti- k_T algorithm with a distance parameter of 0.1.

Particle-level jets are constructed by clustering all stable particles, excluding the lepton, with the anti- k_T algorithm using a distance parameter of 0.4. To determine if a particle-level jet originated from a b quark, b hadrons are included in the clustering of jets, but with the magnitude of the four-momentum of the b hadron scaled to a negligible value. The b hadrons can then be clustered into jets without affecting the kinematic properties of the jet. A jet with a b hadron among its constituents is considered to have originated from a b quark. The particle-level p_T^{miss} is calculated from all stable visible particles. The differential $t\bar{t}$ production cross sections are measured in a visible phase space, which is chosen to be the same for both e+jets and μ +jets channels, and to closely resemble the criteria used to select events in data. Particle-level objects are used to define the common visible phase space of $t\bar{t}$ events for both e+jets and μ +jets channels, all within $|\eta| < 2.4$, which requires exactly one electron or muon with $p_T > 26$ GeV, and no additional electrons or muons with $p_T > 15$ GeV. The event must also contain at least three particle-level jets with $p_T > 30$ GeV, and one jet with $p_T > 20$ GeV. Two of these particle-level jets must also be tagged as originating from a b quark. The particle-level jet selection differs from the reconstructed jet selection in order to minimize the number of events that are selected at the reconstruction level, but do not pass the particle-level selection cuts. The H_T , S_T , and N_{jets} variables are calculated at the particle level with respect to all particle-level jets with $p_T > 20$ GeV and $|\eta| < 2.4$.

The yield of $t\bar{t}$ events in data is obtained by subtracting the contribution of each background process. The contribution of $t\bar{t}$ events that satisfy the selection criteria, but do not enter the visible phase space at particle level, is estimated from simulation and also subtracted from the data. This amounts to approximately 7% of all $t\bar{t}$ events and are predominately those in which one of the jets fails the particle-level jet selection, but passes the reconstructed jet selection because of the resolution of the detector. No selection is applied on the decay channel of the top quarks, so the phase space does not exclusively contain semileptonic (electron or muon) $t\bar{t}$ events. In particular, there are contributions from events where one top quark decays to a tau lepton and subsequently to an electron or muon, or where both top quarks decay leptonically but one lepton is not within the acceptance.

5.2 Unfolding and cross section calculation

For each kinematic event variable the yield of $t\bar{t}$ events in each bin is unfolded to correct for the detector acceptance, efficiency, and bin-to-bin migrations stemming from the detector resolution to obtain the yield of $t\bar{t}$ events in the visible phase space at the particle level. The bin widths are chosen to give a low level of bin-to-bin migration, and are always greater than the detector resolution.

A response matrix, constructed using the POWHEG+PYTHIA sample, relates the kinematic event distributions at reconstruction level to those at particle level. The response matrix also includes efficiency and acceptance corrections. Unfolding is performed by inverting the response matrix, based on a least-squares fit with Tikhonov regularization, implemented in the TUNFOLD software framework [53]. Regularization dampens nonphysical fluctuations in the unfolded $t\bar{t}$ yields, and the regularization parameter is chosen by minimizing the average global correlation between the bins of each variable.

The yields of $t\bar{t}$ events are unfolded separately in the e+jets and μ +jets channels and then combined after unfolding, giving the total number of $t\bar{t}$ events at particle level in the visible phase space, $N_{t\bar{t}}$. The normalized differential cross section with respect to each variable, X , can then

be calculated using

$$\frac{1}{\sigma_{\text{tt}}^{\text{vis}}} \frac{d\sigma_{\text{tt}}^i}{dX} = \frac{1}{\sum_j N_{\text{tt}}^j} \frac{N_{\text{tt}}^i}{\Delta X^i}, \quad (1)$$

where $\sigma_{\text{tt}}^{\text{vis}}$ is the total $\text{t}\bar{\text{t}}$ production cross section in the visible phase space, σ_{tt}^i is the $\text{t}\bar{\text{t}}$ production cross section in bin i , $N_{\text{tt}}^{i(j)}$ is the number of $\text{t}\bar{\text{t}}$ events in bin $i(j)$ after unfolding, and ΔX^i is the width of bin i . The absolute differential cross section can be calculated as

$$\frac{d\sigma_{\text{tt}}^i}{dX} = \frac{N_{\text{tt}}^i}{\mathcal{L} \Delta X^i}, \quad (2)$$

where \mathcal{L} is the integrated luminosity of the data.

6 Systematic uncertainties

Sources of systematic uncertainties are evaluated and propagated to the final result by recalculating the response matrix with a modified $\text{t}\bar{\text{t}}$ simulation or by modifying the background predictions.

The uncertainty in the integrated luminosity of the data is estimated to be $\pm 2.5\%$ [54]. The uncertainty in the number of additional inelastic interactions in the same or nearby bunch crossings is estimated by varying the total proton-proton inelastic cross section by $\pm 4.6\%$ [55]. This cross section is used in determining the distribution of additional inelastic interactions in data, which is used to correct the simulation.

The uncertainty in the efficiency of the b quark jet identification and mistagging rate in the simulation is taken as the uncertainty in the p_{T} , $|\eta|$, and flavor-dependent correction factors [49]. The uncertainties in the lepton trigger, reconstruction, and identification correction factors are similarly propagated to the final results.

The uncertainties in the jet energy scale (JES) and jet energy resolution (JER) are estimated as functions of jet p_{T} and $|\eta|$ [47]. The uncertainty in the JES is also propagated into the calculation of $p_{\text{T}}^{\text{miss}}$. Additional uncertainties in the p_{T} of electrons, muons, tau leptons and other unclustered PF candidates, that are used in the calculation of $p_{\text{T}}^{\text{miss}}$, are considered and found to be negligible.

The uncertainties in the normalization of the single top quark and V+jets background sources are based on measurements performed in [56–58] and take into account an extrapolation to the current analysis phase space. They are estimated to be $\pm 30\%$ and $\pm 50\%$ respectively and typically result in a normalization uncertainty that is negligible. The uncertainty in the normalization and shape of the multijet QCD background is estimated by using alternative control regions containing conversion electrons in the e+jets channel and muons with $I_{\text{rel}} > 0.3$ in the μ +jets channel. This effectively varies the total normalization of the multijet QCD background by up to 60%, and also the shape of the contribution by up to $\pm 30\%$ in any one bin, but is found to result in a negligible uncertainty after unfolding, except at large $|\eta^\ell|$.

Uncertainties in the top quark mass are estimated by using simulated $\text{t}\bar{\text{t}}$ samples where the top quark mass has been varied up and down by 1 GeV, which is comparable to the uncertainty in the measured top quark mass [59].

The uncertainty from the PDF is estimated by considering 100 independent replicas of NNPDF30_nlo_as_0118. The RMS of the uncertainties originating from the variation of each replica is taken as the PDF uncertainty. The uncertainty resulting from using the

NNPDF30_nlo_as_0118 set derived with varied values of α_S is combined in quadrature with the PDF uncertainty.

The uncertainty arising from the mismodeling of the top quark p_T spectrum is estimated by reweighting the p_T distribution in simulation to match that measured by the previous measurements [7, 8]. The reweighting varies the yield of simulated $t\bar{t}$ events in the bins of the measurement by up to 20%, and results in a negligible uncertainty in the measured cross section.

Several sources of uncertainty for the modeling of the parton shower in the simulated POWHEG+PYTHIA sample are considered.

The uncertainty originating from the parton shower scale used when simulating the initial-state radiation is estimated by varying the scale up and down by a factor of two. Similarly the uncertainty originating from the scale for final-state radiation, which is constrained by measurements made at the LEP collider [60], is estimated by varying the scale up and down by a factor of $\sqrt{2}$. The renormalization and factorization scales used in the matrix-element calculations are also varied independently by factors of 0.5 and 2. An additional variation is performed where both scales are varied simultaneously by the same factors. The shower scale uncertainty is defined as the envelope of the parton shower scale uncertainties and the matrix-element scale uncertainties.

The systematic uncertainty in matching the matrix-element to the parton shower (ME/PS) is determined by varying the parameter h_{damp} , which regulates the high- p_T radiation by damping real emission generated in POWHEG, within its uncertainties. The parameter is set to $h_{\text{damp}} = 1.58^{+0.66}_{-0.59}$ multiplied by the mass of the top quark in the CUETP8M2T4 tune [19]. The parameters controlling the underlying event in the CUETP8M2T4 tune are also varied to estimate the uncertainty in this source [19].

The uncertainty in the modeling of the momentum transfer from b quarks to b hadrons is estimated by reweighting the tuned quantity $x_b = p_T(\text{B}) / p_T(\text{b jet})$ for each particle-level b-tagged jet within its uncertainties, where $p_T(\text{B})$ is the transverse momentum of the b hadron, and $p_T(\text{b jet})$ is the transverse momentum of the particle-level b-tagged jet. The difference when using an alternative model (the Peterson model [61]) for the fragmentation of b quarks is also included as an additional uncertainty. The energy response of b jets is sensitive to the single-lepton branching fractions of b hadrons, and the uncertainty originating from the choice of branching fractions in the POWHEG+PYTHIA simulation is estimated by reweighting the branching fractions to those reported in Ref. [59].

The effects of any mismodeling of the color reconnection in the simulation are estimated by comparing the cross sections obtained with samples including and excluding the effects of color reconnection on the decay products of the top quarks (Early resonance decays). A comparison to two samples obtained with alternative models of color reconnection are also included, one where QCD color rules are considered in the simulation of the color reconnection (QCD-based) [62], and another where gluons can be moved to different color strings during the simulation of the color reconnection (Gluon move) [63].

The statistical uncertainty arising from the finite size of the POWHEG+PYTHIA sample, which is used to construct the nominal response matrix, is propagated to the final measurement. This uncertainty is negligible.

Each source of systematic uncertainty is summarised for each variable in Table 1, where the minimum and maximum relative uncertainty in the normalized differential cross section (over

all bins) are shown. The minimum and maximum of the total relative uncertainty over all bins are also shown. The dominant uncertainty in the measurement of the normalized cross sections comes from the uncertainty in the JES. Other significant uncertainties come from the theoretical modeling of $t\bar{t}$ production in simulation, in particular from the uncertainty in the shower scale for final-state radiation. A similar table for the absolute differential cross section uncertainties is shown in Appendix C. The uncertainty in the JES is also significant in the measurements of the absolute cross sections, however the uncertainty in the final-state radiation scale becomes dominant. The total uncertainty from all sources in the normalized cross section is typically below 5% in each bin, and can be as large as 21%. For the measurements of the absolute cross section, the total uncertainty is typically 10%, and can be as large as 22%.

Table 1: The upper and lower bounds, in %, from each source of systematic uncertainty in the normalized differential cross section, over all bins of the measurement for each variable. The bounds of the total relative uncertainty are also shown.

7 Cross section results

The normalized differential $t\bar{t}$ production cross sections with respect to N_{jets} is shown in Fig. 3, with respect to H_T and S_T in Fig. 4, with respect to p_T^{miss} and p_T^W in Fig. 5 and with respect to p_T^ℓ and $|\eta^\ell|$ in Fig. 6. Tabulated results are listed in Appendix A. Measurements of the absolute differential $t\bar{t}$ production cross sections are shown in Figs. 7, 8, 9 and 10, and tabulated in Appendix B. In each figure, the measured cross section is compared with the predictions from several combinations of matrix-element and parton shower generators, namely POWHEG+PYTHIA, POWHEG+HERWIG++, MG5_aMC@NLO-NLO, and MG5_aMC@NLO-LO. Each measured cross section is also compared to the POWHEG+PYTHIA generator after varying the shower scales and the h_{damp} parameter used in generating the sample within their uncertainties, and also after reweighting the top quark p_T as described in Section 6.

The level of agreement between the measured and predicted differential cross sections are determined through a χ^2 test, where the full covariance matrix, including the correlations between the statistical and systematic uncertainties in each bin of the measurements, is taken into account. The results, including the p -value of each test, are shown in Tables 2 and 3.

The predictions of the POWHEG+PYTHIA model are consistent with data for the N_{jets} , p_T^{miss} , S_T , and p_T^ℓ distributions. In particular, the prediction of the N_{jets} distribution has a χ^2 per degree of freedom of 2/5 for the normalized and 2.3/6 for the absolute cross section measurement. The jet multiplicity from previous 8 TeV measurements was used in deriving the CUETP8M2T4 tune [19], and this confirms that the tune continues to accurately describe the jet multiplicity on a larger data set with a higher \sqrt{s} . On the other hand, tensions are observed for the H_T , p_T^W and $|\eta^\ell|$ variables. An additional χ^2 calculation between the POWHEG+PYTHIA model and unfolded data is performed, including the theoretical uncertainties within the generator and their correlations to uncertainties in the unfolded data. The result of this test demonstrates that the theoretical uncertainties in the POWHEG+PYTHIA model cover the differences between the POWHEG+PYTHIA model and the unfolded data in the phase space analyzed.

The POWHEG+HERWIG++ and MG5_aMC@NLO-NLO models are broadly consistent with the unfolded data, even without including the theoretical uncertainties in the χ^2 test, with the exception of N_{jets} in POWHEG+HERWIG++ and $|\eta^\ell|$ in MG5_aMC@NLO-NLO. Without these uncertainties, the MG5_aMC@NLO-LO model is not compatible with any kinematic event distribution in the unfolded data presented here.

The effect of the regularization in the unfolding procedure is investigated by unfolding without regularization, which typically results in a small change in the χ^2 . When unfolding without regularization, the largest changes in χ^2 for the normalized cross sections are for the H_T distribution with the MG5_aMC@NLO-NLO model, where the χ^2 per degree of freedom increases from 12/12 to 15/12, and for the p_T^{miss} distribution in the POWHEG+PYTHIA model (including the model theoretical uncertainties), where the χ^2 per degree of freedom decreases from 2.9/5 to 2.1/5. The effects on the χ^2 for all other variables and models are small. The χ^2 does not change for the p_T^ℓ and $|\eta^\ell|$ distributions for any model when unfolding without regularization.

The vertical bars on the data represent the statistical and systematic uncertainties added in quadrature. The bottom panels show the ratio of the predictions to the data.

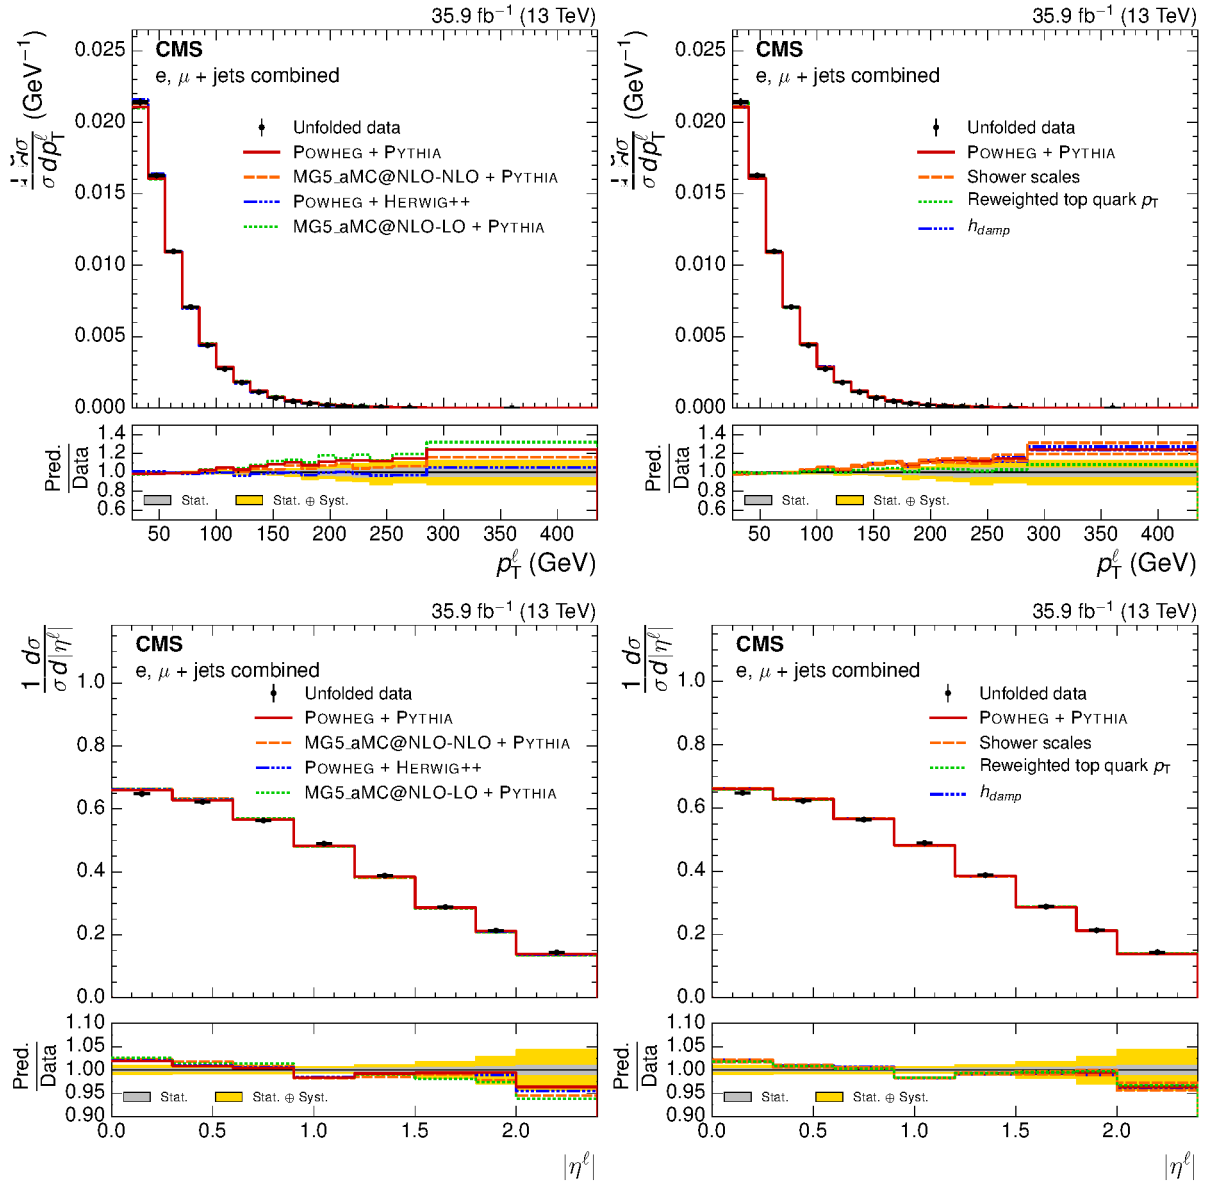

Figure 6: Normalized p_T^ℓ (upper) and $|\eta^\ell|$ (lower) differential $t\bar{t}$ cross sections, compared to different $t\bar{t}$ simulations in the left plots, and compared to the POWHEG+PYTHIA simulation after varying the shower scales, and h_{damp} parameter, within their uncertainties, in the right plots. The vertical bars on the data represent the statistical and systematic uncertainties added in quadrature. The bottom panels show the ratio of the predictions to the data.

Figure 7: Absolute N_{jets} differential $t\bar{t}$ cross sections, compared to different $t\bar{t}$ simulations in the left plots, and compared to the POWHEG+PYTHIA simulation after varying the shower scales, and h_{damp} parameter, within their uncertainties, in the right plots. The vertical bars on the data represent the statistical and systematic uncertainties added in quadrature. The bottom panels show the ratio of the predictions to the data.

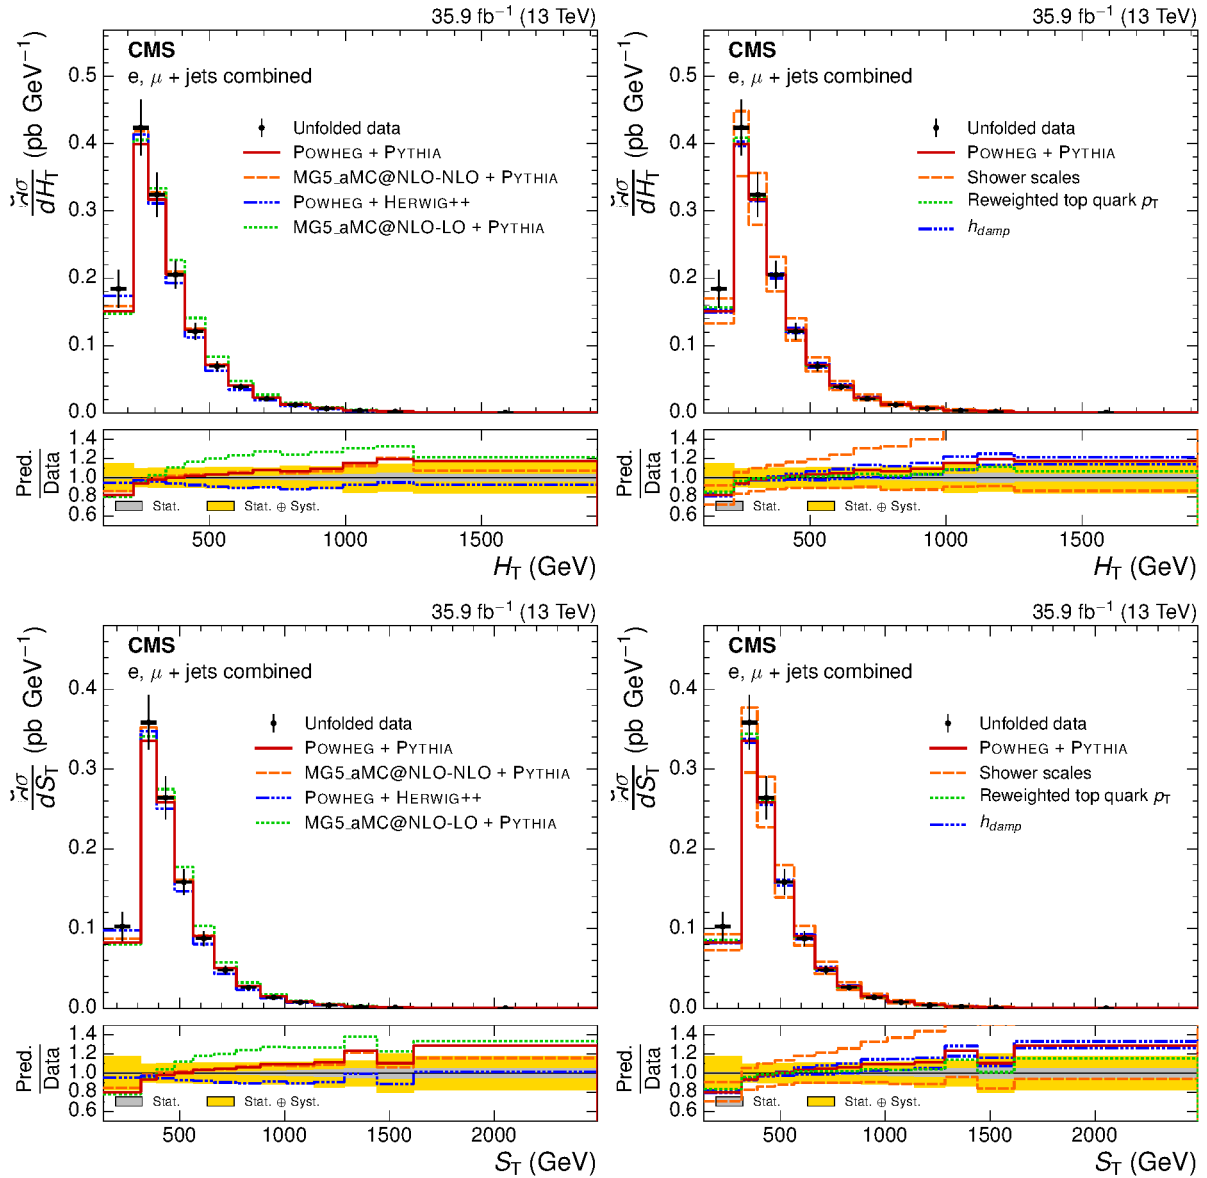

Figure 8: Absolute H_T (upper) and S_T (lower) differential $t\bar{t}$ cross sections, compared to different $t\bar{t}$ simulations in the left plots, and compared to the POWHEG+PYTHIA simulation after varying the shower scales, and h_{damp} parameter, within their uncertainties, in the right plots. The vertical bars on the data represent the statistical and systematic uncertainties added in quadrature. The bottom panels show the ratio of the predictions to the data.

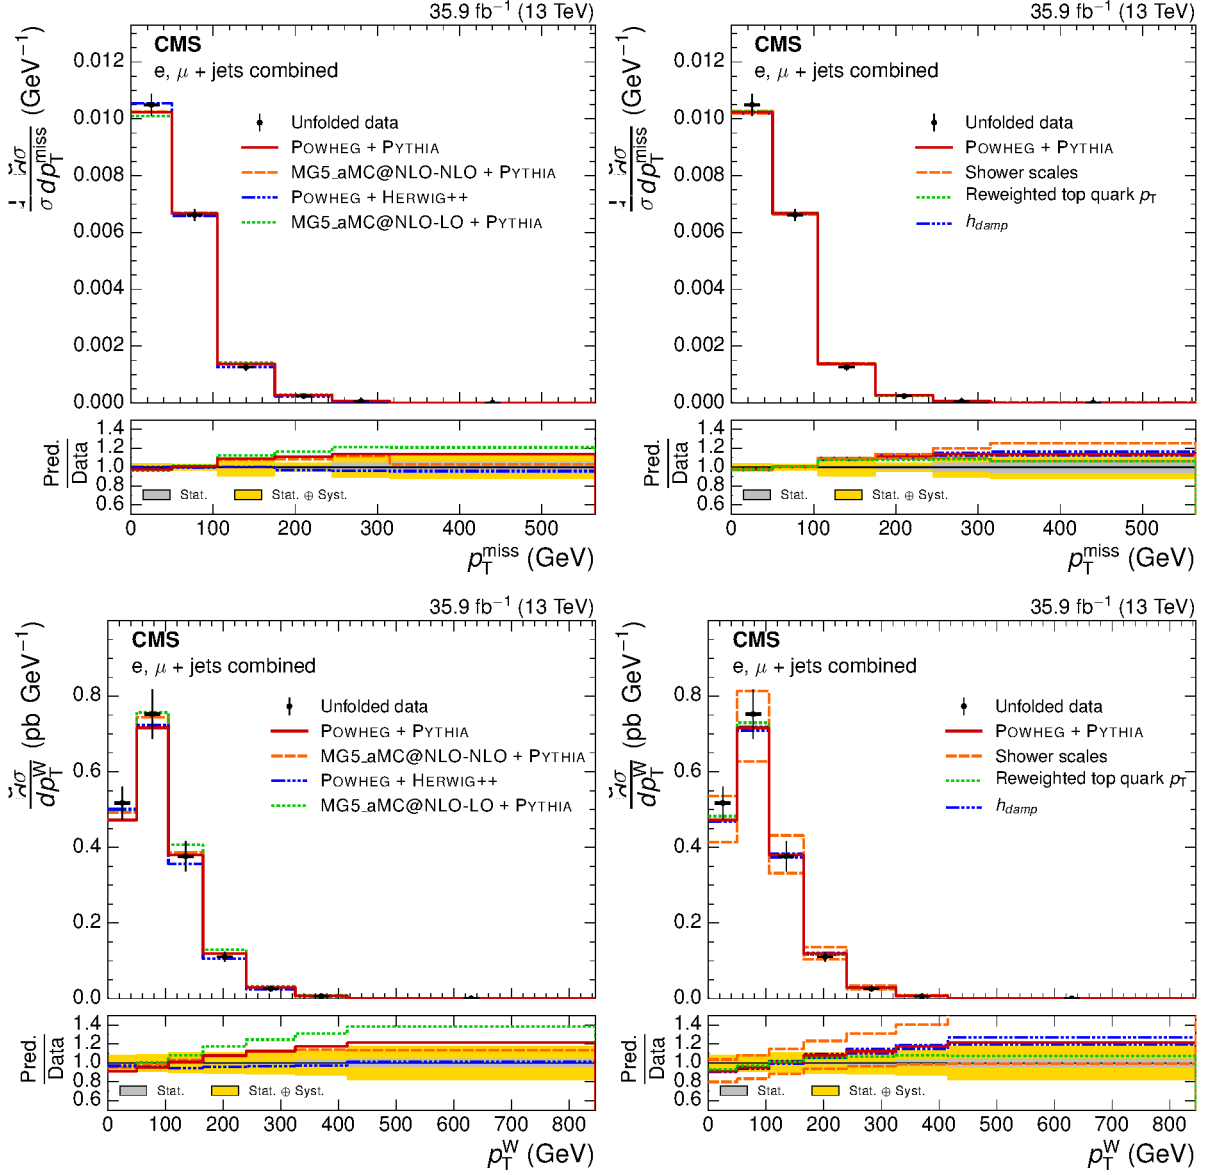

Figure 9: Absolute p_T^{miss} (upper) and p_T^W (lower) differential $t\bar{t}$ cross sections, compared to different $t\bar{t}$ simulations in the left plots, and compared to the POWHEG+PYTHIA simulation after varying the shower scales, and h_{damp} parameter, within their uncertainties, in the right plots. The vertical bars on the data represent the statistical and systematic uncertainties added in quadrature. The bottom panels show the ratio of the predictions to the data.

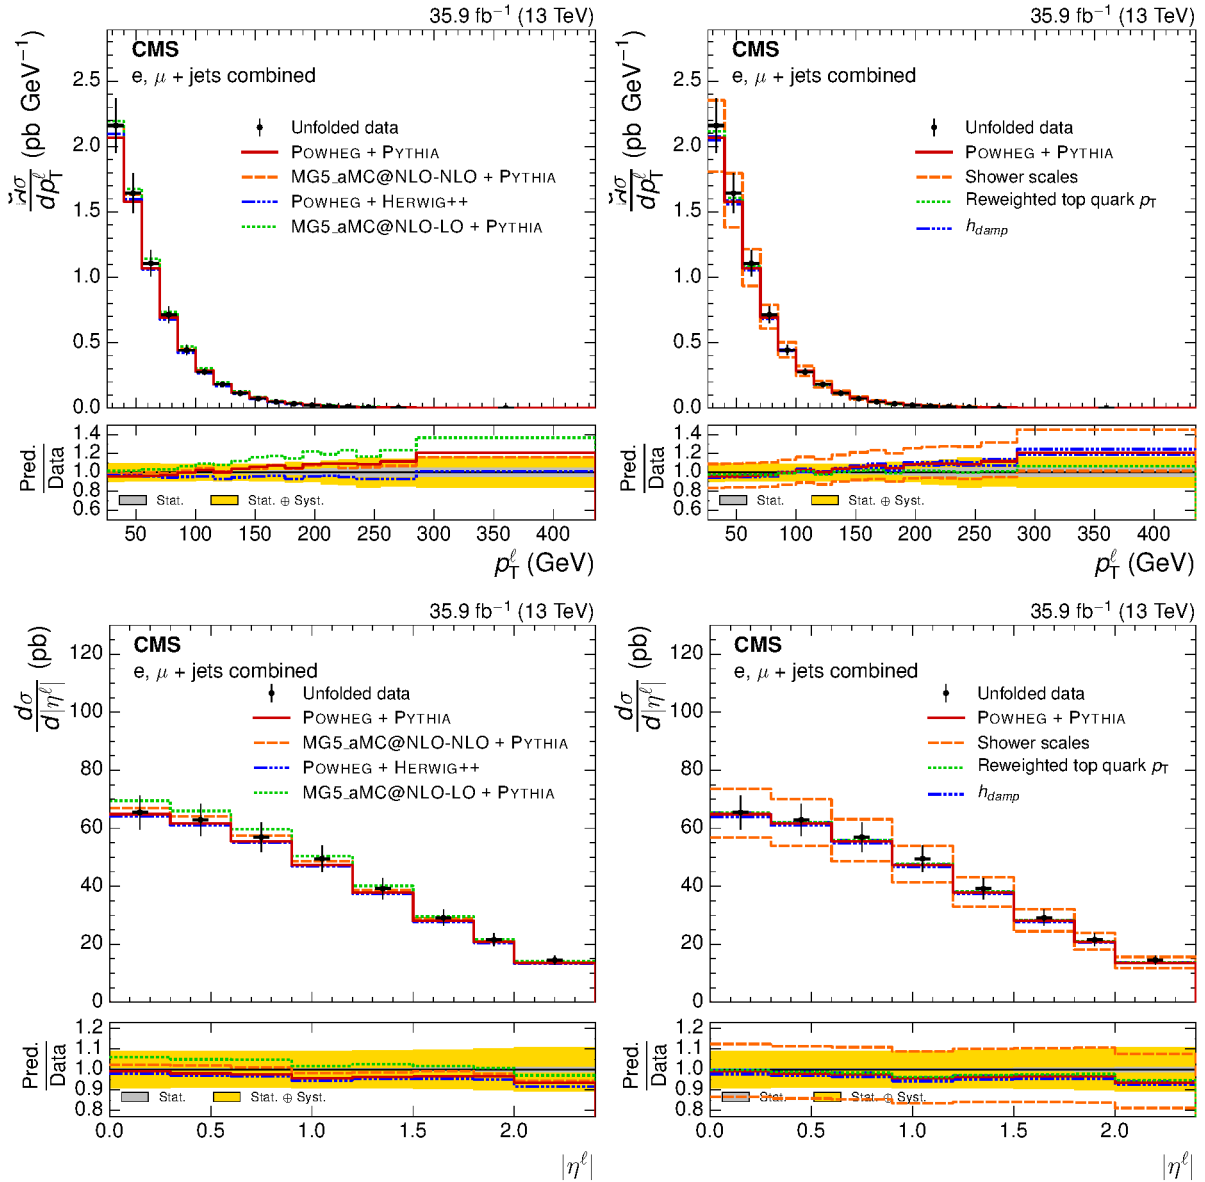

Figure 10: Absolute p_T^ℓ (upper) and $|\eta^\ell|$ (lower) differential $t\bar{t}$ cross sections, compared to different $t\bar{t}$ simulations in the left plots, and compared to the POWHEG+PYTHIA simulation after varying the shower scales, and h_{damp} parameter, within their uncertainties, in the right plots. The vertical bars on the data represent the statistical and systematic uncertainties added in quadrature. The bottom panels show the ratio of the predictions to the data.

8 Summary

Normalized and absolute differential $t\bar{t}$ production cross sections with respect to several kinematic event variables are measured at the particle level in a visible phase space region. The results are based on proton-proton collision data at $\sqrt{s} = 13$ TeV, collected by the CMS experiment with an integrated luminosity of 35.9 fb^{-1} . The total cross section is observed to be consistent with previous results and next-to-next-to-leading-order calculations, and the differential measurements are compared to several $t\bar{t}$ production models: POWHEG+PYTHIA, POWHEG+HERWIG++, MG5_aMC@NLO-LO, and MG5_aMC@NLO-NLO.

The POWHEG+PYTHIA simulation is found to be generally consistent with the data, with residual differences covered by theoretical uncertainties. The jet multiplicity distribution is particularly well-modeled, having been tuned on LHC 8 TeV data. The POWHEG+HERWIG++ and MG5_aMC@NLO-NLO models are shown to be consistent with data for most kinematic event variables, while the MG5_aMC@NLO-LO model does not provide an accurate description of any variable measured in the data.

It is expected that the results presented here will be useful for tuning $t\bar{t}$ generators and models in the future. To facilitate this, the measurements presented here have been implemented in the RIVET framework and will be available to the wider community.

Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMFWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); SENESCYT (Ecuador); MoER, ERC IUT, and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); OTKA and NIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS, RFBR and RAEP (Russia); MESTD (Serbia); SEIDI, CPAN, PCTI and FEDER (Spain); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR, and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

1440–1615	1.21×10^{-3}	5.3	22
1615–2490	2.44×10^{-4}	4.6	20

Table 14: Results of the absolute differential cross sections with relative uncertainties in the combined channel with respect to p_T^{miss} .

p_T^{miss} (GeV)	$\frac{d\sigma}{dp_T^{\text{miss}}}$ (pb GeV $^{-1}$)	Stat. unc. (%)	Syst. unc. (%)
0–50	1.04	0.21	11
50–105	0.659	0.28	13
105–175	0.129	0.76	18
175–245	2.49×10^{-2}	2.0	13
245–315	6.07×10^{-3}	4.5	17
315–565	7.80×10^{-4}	5.8	19

Table 15: Results of the absolute differential cross sections with relative uncertainties in the combined channel with respect to p_T^W .

p_T^W (GeV)	$\frac{d\sigma}{dp_T^W}$ (pb GeV $^{-1}$)	Stat. unc. (%)	Syst. unc. (%)
0–50	0.514	0.41	11
50–105	0.745	0.25	11
105–165	0.375	0.39	13
165–240	0.112	0.70	12
240–325	2.65×10^{-2}	1.4	13
325–415	6.46×10^{-3}	2.8	14
415–845	5.60×10^{-4}	4.1	18

Table 16: Results of the absolute differential cross sections with relative uncertainties in the combined channel with respect to p_T^ℓ .

p_T^ℓ (GeV)	$\frac{d\sigma}{dp_T^\ell}$ (pb GeV $^{-1}$)	Stat. unc. (%)	Syst. unc. (%)
26–40	2.14	0.39	13
40–55	1.63	0.28	11
55–70	1.11	0.33	11
70–85	0.721	0.41	9.9
85–100	0.448	0.53	9.9
100–115	0.278	0.68	9.6
115–130	0.183	0.86	9.6
130–145	0.115	1.1	9.0
145–160	7.34×10^{-2}	1.4	9.3
160–175	4.84×10^{-2}	1.9	9.4
175–190	3.37×10^{-2}	2.3	12
190–205	2.21×10^{-2}	3.0	10
205–220	1.53×10^{-2}	3.8	13
220–235	1.08×10^{-2}	4.7	15
235–255	7.41×10^{-3}	4.6	17
255–285	4.32×10^{-3}	4.5	15
285–435	9.61×10^{-4}	4.4	17

Table 17: Results of the absolute differential cross sections with relative uncertainties in the combined channel with respect to $|\eta^\ell|$.

$ \eta^\ell $	$\frac{d\sigma}{d \eta^\ell }$ (pb)	Stat. unc. (%)	Syst. unc. (%)
0–0.30	65.0	0.46	10
0.30–0.60	62.4	0.50	10
0.60–0.90	56.9	0.45	9.7
0.90–1.20	49.2	0.48	10
1.20–1.50	39.2	0.56	9.9
1.50–1.80	29.2	0.76	10
1.80–2.00	21.5	0.91	11
2.00–2.40	14.6	1.1	11

C Tabulated minimum and maximum relative uncertainties for absolute cross sections

Table 18: The upper and lower bounds, in %, from each source of systematic uncertainty in the absolute differential cross section, over all bins of the measurement for each variable. The bounds of the total relative uncertainty are also shown.

Relative uncertainty source (%)	N_{jets}	H_T	S_T	p_T^{miss}	p_T^W	p_T^c	$ \eta^c $

†: Deceased

- 1: Also at Vienna University of Technology, Vienna, Austria
- 2: Also at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France
- 3: Also at Universidade Estadual de Campinas, Campinas, Brazil
- 4: Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil
- 5: Also at Université Libre de Bruxelles, Bruxelles, Belgium
- 6: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
- 7: Also at Joint Institute for Nuclear Research, Dubna, Russia
- 8: Also at Cairo University, Cairo, Egypt
- 9: Also at Helwan University, Cairo, Egypt
- 10: Now at Zewail City of Science and Technology, Zewail, Egypt
- 11: Also at Department of Physics, King Abdulaziz University, Jeddah, Saudi Arabia
- 12: Also at Université de Haute Alsace, Mulhouse, France
- 13: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
- 14: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
- 15: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany
- 16: Also at University of Hamburg, Hamburg, Germany
- 17: Also at Brandenburg University of Technology, Cottbus, Germany
- 18: Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary
- 19: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
- 20: Also at Institute of Physics, University of Debrecen, Debrecen, Hungary
- 21: Also at Indian Institute of Technology Bhubaneswar, Bhubaneswar, India
- 22: Also at Institute of Physics, Bhubaneswar, India
- 23: Also at Shoolini University, Solan, India
- 24: Also at University of Visva-Bharati, Santiniketan, India
- 25: Also at University of Ruhuna, Matara, Sri Lanka
- 26: Also at Isfahan University of Technology, Isfahan, Iran
- 27: Also at Yazd University, Yazd, Iran
- 28: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
- 29: Also at Università degli Studi di Siena, Siena, Italy
- 30: Also at INFN Sezione di Milano-Bicocca; Università di Milano-Bicocca, Milano, Italy
- 31: Also at Laboratori Nazionali di Legnaro dell'INFN, Legnaro, Italy
- 32: Also at International Islamic University of Malaysia, Kuala Lumpur, Malaysia
- 33: Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia
- 34: Also at Consejo Nacional de Ciencia y Tecnología, Mexico city, Mexico
- 35: Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland

- 36: Also at Institute for Nuclear Research, Moscow, Russia
- 37: Now at National Research Nuclear University 'Moscow Engineering Physics Institute' (MEPhI), Moscow, Russia
- 38: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
- 39: Also at University of Florida, Gainesville, USA
- 40: Also at P.N. Lebedev Physical Institute, Moscow, Russia
- 41: Also at California Institute of Technology, Pasadena, USA
- 42: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia
- 43: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
- 44: Also at INFN Sezione di Pavia; Università di Pavia, Pavia, Italy
- 45: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
- 46: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy
- 47: Also at National and Kapodistrian University of Athens, Athens, Greece
- 48: Also at Riga Technical University, Riga, Latvia
- 49: Also at Universität Zürich, Zurich, Switzerland
- 50: Also at Stefan Meyer Institute for Subatomic Physics (SMI), Vienna, Austria
- 51: Also at Adiyaman University, Adiyaman, Turkey
- 52: Also at Istanbul Aydin University, Istanbul, Turkey
- 53: Also at Mersin University, Mersin, Turkey
- 54: Also at Piri Reis University, Istanbul, Turkey
- 55: Also at Gaziosmanpasa University, Tokat, Turkey
- 56: Also at Izmir Institute of Technology, Izmir, Turkey
- 57: Also at Necmettin Erbakan University, Konya, Turkey
- 58: Also at Marmara University, Istanbul, Turkey
- 59: Also at Kafkas University, Kars, Turkey
- 60: Also at Istanbul Bilgi University, Istanbul, Turkey
- 61: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
- 62: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
- 63: Also at Monash University, Faculty of Science, Clayton, Australia
- 64: Also at Instituto de Astrofísica de Canarias, La Laguna, Spain
- 65: Also at Bethel University, ST. PAUL, USA
- 66: Also at Utah Valley University, Orem, USA
- 67: Also at Purdue University, West Lafayette, USA
- 68: Also at Beykent University, Istanbul, Turkey
- 69: Also at Bingol University, Bingol, Turkey
- 70: Also at Erzincan University, Erzincan, Turkey
- 71: Also at Sinop University, Sinop, Turkey
- 72: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
- 73: Also at Texas A&M University at Qatar, Doha, Qatar
- 74: Also at Kyungpook National University, Daegu, Korea
