

Search for dark matter produced in association with a single top quark or a top quark pair in proton-proton collisions at $\sqrt{s} = 13$ TeV

The CMS Collaboration*

Abstract

A search for dark matter produced in association with top quarks in proton-proton collisions at a center-of-mass energy of 13 TeV is presented. The data set used corresponds to an integrated luminosity of 35.9 fb^{-1} recorded with the CMS detector at the LHC. Whereas previous searches for neutral scalar or pseudoscalar mediators considered dark matter production in association with a top quark pair only, this analysis also includes production modes with a single top quark. The results are derived from the combination of multiple selection categories that are defined to target either the single top quark or the top quark pair signature. No significant deviations with respect to the standard model predictions are observed. The results are interpreted in the context of a simplified model in which a scalar or pseudoscalar mediator particle couples to a top quark and subsequently decays into dark matter particles. Scalar and pseudoscalar mediator particles with masses below 290 and 300 GeV, respectively, are excluded at 95% confidence level, assuming a dark matter particle mass of 1 GeV and mediator couplings to fermions and dark matter particles equal to unity.

Submitted to the Journal of High Energy Physics

1 Introduction

Astrophysical observations provide evidence of the existence of nonluminous matter that can be inferred from gravitational effects on galaxies and other large scale objects in the Universe. While the nature of this dark matter (DM) is still unknown, a compelling candidate is the so-called weakly interacting massive particle [1]. This new particle is predicted to have weak interactions with standard model (SM) particles, allowing for direct- and indirect-detection experiments, as well as for searches at collider experiments.

Among all the possible interactions between the SM and DM sectors, it is of particular interest to investigate interactions mediated by a new neutral scalar or pseudoscalar particle that decays into DM particles, as these can be easily accommodated in models containing extended Higgs boson sectors [2–5]. Assuming that this DM scenario respects the principle of minimal flavor violation [6, 7], the interactions of this new spin-0 mediator particle follow the same Yukawa coupling structure as in the SM. Therefore, the mediator would couple preferentially to heavy third-generation quarks. Assuming the DM particles to be Dirac fermions, the interaction Lagrangian terms for the production of a scalar (ϕ) or pseudoscalar (a) mediator particle can be expressed as:

$$\mathcal{L}_\phi \supset g_\chi \phi \bar{\chi} \chi + \frac{g_q \phi}{\sqrt{2}} \sum_f (y_f \bar{f} f), \quad (1)$$

$$\mathcal{L}_a \supset i g_\chi a \bar{\chi} \gamma^5 \chi + \frac{i g_q a}{\sqrt{2}} \sum_f (y_f \bar{f} \gamma^5 f), \quad (2)$$

where the sum runs over the SM fermions f , $y_f = \sqrt{2} m_f / v$ represents the Yukawa couplings, $v = 246 \text{ GeV}$ is the Higgs field vacuum expectation value, g_χ is the DM-mediator coupling, and g_q is the fermion-mediator coupling. The mediator particle subsequently decays into DM particles, which escape detection and leave an imbalance of momentum in the transverse plane, referred to as p_T^{miss} . Several theoretical studies of these types of models have been performed, in which the third-generation quark is either a top or bottom quark, leading to the production of DM in association with a pair of top ($t\bar{t}$ +DM) or bottom ($b\bar{b}$ +DM) quarks, respectively [8–11]. The main production diagram for $t\bar{t}$ +DM processes is shown in Fig. 1 (upper left).

Previous searches in these final states have been carried out by the ATLAS and CMS Collaborations at center-of-mass energies of 8 TeV [12, 13] and 13 TeV [14–16]. While the former results are based on an effective field theory (EFT) approach, the latter ones are interpreted in the context of simplified DM scenarios, where the mediator particle is explicitly modeled in the interaction. These interpretations have so far neglected the contribution from DM production in association with a single top quark (t/\bar{t} +DM) in which the interaction is mediated by a neutral spin-0 particle, as pointed out in Ref. [17]. As in the SM, the single top quark is produced through processes mediated by a virtual t channel (Fig. 1, upper right) or through associated production with a W boson (Fig. 1, lower left and right) [17]. While the s channel production of a W boson is also possible, this process is found to have a negligible contribution for this search. The neutral DM mediator particle is then produced either by radiation from the top quark or via top quark fusion, as described in Ref. [18] for the associated production of DM with a top quark pair.

In this search, t/\bar{t} +DM processes mediated by a neutral spin-0 particle are investigated for the first time. This additional production mechanism is predicted by the same interactions described in Eqs. (1) and (2) that also predict $t\bar{t}$ +DM events. For this reason, in the presented search t/\bar{t} +DM and $t\bar{t}$ +DM processes are both considered. Searches for similar final states referred to as “monotop”, which involve the production of a top quark and DM particles but

Figure 1: Principal production diagrams for the associated production at the LHC of dark matter with a top quark pair (upper left) or a single top quark with associated t channel W boson production (upper right) or with associated tW production (lower left and right).

without additional jets or W bosons, have been conducted by the CDF experiment [19] at the Fermilab Tevatron, by the ATLAS and CMS Collaborations [20, 21] at the CERN LHC at center-of-mass energies of 8 TeV, and at 13 TeV by the CMS Collaboration [22]. The underlying simplified models explored in these results, unlike the one presented in Eqs. (1) and (2), assume either the resonant production of a $+2/3$ charged and colored spin-0 boson that decays into a right-handed top quark and one DM particle, or a spin-1 mediator with flavor changing neutral current interactions. Considering these models, in addition to the DM particle, only one top quark is assumed to be produced in the final state, unlike the t/\bar{t} +DM processes considered in this search where the top quark is produced through SM-like diagrams alongside a light quark or a W boson (Fig. 1).

In this paper we present a search for an excess of events above the SM background in the p_T^{miss} spectrum, as expected for the DM scenarios discussed earlier, for events that contain exactly one lepton (electron or muon) or zero leptons, henceforth assigned to the “single-lepton” (SL) region or to the “all-hadronic” (AH) region, respectively. The sensitivity of this analysis is improved beyond that of previous analyses by introducing a categorization of these signatures and new discriminating variables, as discussed in more detail in Section 4.

2 The CMS detector and event reconstruction

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter (HCAL), each composed of a barrel and two endcap sections. Forward calorimeters extend the pseudorapidity (η) coverage provided by the barrel and endcap detectors. Muons are detected in gas-ionization chambers embedded in the steel flux-return yoke outside the solenoid. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [23].

Events of interest are selected using a two-tiered trigger system [24]. The first level, composed of custom hardware processors, uses information from the calorimeters and muon detectors to select events at a rate of around 100 kHz within a time interval of less than $4 \mu\text{s}$. The second level, known as the high-level trigger, consists of a farm of processors running a version of the full event reconstruction software optimized for fast processing, and reduces the event rate to around 1 kHz before data storage.

The particle-flow (PF) algorithm [25] aims to reconstruct and identify each individual particle in an event, with an optimized combination of information from the various elements of the CMS detector. The energy of photons is obtained directly from the ECAL measurement and corrected for zero-suppression effects. The energy of electrons is obtained from a combination of the electron momentum at the primary interaction vertex as determined by the tracker, the energy of the corresponding ECAL cluster, and the energy sum of all bremsstrahlung photons spatially compatible with originating from the electron track. The muon track is obtained from the combination of central tracker and muon system information, and its curvature provides an estimate of the momentum. The energy of charged hadrons is determined from a combination of their momentum measured in the tracker and the matching ECAL and HCAL energy deposits, corrected for zero-suppression effects and for the response function of the calorimeters to hadronic showers. Finally, the energy of neutral hadrons is obtained from the corresponding corrected ECAL and HCAL energy.

The reconstructed vertex with the largest value of summed physics-object p_T^2 , where p_T is the transverse momentum, is taken to be the primary proton-proton (pp) interaction vertex. The physics objects are the jets and the associated \vec{p}_T^{miss} , taken as the negative vector p_T sum of those jets. For each event, hadronic jets are clustered from the particles reconstructed with PF (PF candidates) using the infrared- and collinear-safe anti- k_T algorithm [26, 27] with a distance parameter of 0.4. The jet momentum is determined as the vectorial sum of all particle momenta in the jet, and is found from simulation to be within 5 to 10% of the parton's generated momentum over the whole p_T spectrum and detector acceptance. Additional pp interactions within the same or nearby bunch crossings (pileup) can contribute additional tracks and calorimetric energy depositions to the jet momentum. To mitigate this effect, tracks identified as originating from pileup vertices are discarded and an offset correction is applied to correct for remaining contributions [28]. Jet energy corrections are derived from simulation and applied to calibrate the jet momentum. In situ measurements of the momentum balance in dijet, photon+jet, Z+jets, and multijet events are used to account for any residual differences in jet energy scale in data and simulation [29]. Additional selection criteria are applied to each jet to remove jets potentially dominated by anomalous contributions from various subdetector components or reconstruction failures [29].

The combined secondary vertex b tagging algorithm (CSVv2) is used to identify jets originating from the hadronization of bottom quarks [30], denoted in the following as “b-tagged jets”. At the operating point of the tagging algorithm chosen for this analysis, the efficiency of identifying b quark jets in simulated tt events is about 80%, integrated over p_T , and the misidentification rate for light-flavor jets is about 1%. Scale factors are applied to the simulated samples in order to reproduce the b tagging performance measured in data.

The missing transverse momentum vector \vec{p}_T^{miss} is defined as the negative vector p_T sum of all PF particles originating from the primary vertex; its magnitude is defined as p_T^{miss} . Jet energy scale and resolution corrections are also propagated to the \vec{p}_T^{miss} calculation.

3 Data sample and simulation

The data used in this search were recorded with the CMS detector in 2016 and correspond to an integrated luminosity of 35.9 fb^{-1} . Several trigger criteria were used to collect the data, either requiring large amounts of p_T^{miss} or the presence of at least one high- p_T lepton (electron or muon). Simulated samples are corrected to reproduce the observed trigger efficiencies in data.

Specifically, events that do not contain leptons are selected if they have p_T^{miss} and missing hadronic activity H_T^{miss} [24] above 120 GeV. This trigger is nearly 100% efficient for events with p_T^{miss} of at least 250 GeV. The second set of triggers requires the presence of at least one isolated electron (muon) with $p_T > 27$ (25) GeV. The corresponding trigger efficiencies are above 90% for leptons with $p_T > 30$ GeV. Trigger efficiencies are measured in data.

Monte Carlo (MC) simulated samples of the main SM backgrounds and of the DM signal processes are used to optimize the event selection, assess our sensitivity to the new-physics scenarios, and form the basis of our background estimation strategy. While the detailed background composition depends on the specific channel, the main sources arise from $t\bar{t}$ +jets, W+jets, and Z+jets production. Simulated events of $t\bar{t}$ +jets production and single top quark processes are generated at next-to-leading order (NLO) in quantum chromodynamics (QCD) using POWHEG v2 and POWHEG v1 [31–33], respectively. For $t\bar{t}$ +jets processes, the top quark p_T distribution is reweighted to reproduce the differential cross section obtained from CMS measurements [34]. Samples of Z+jets, W+jets, and QCD multijet events are generated at leading order (LO) using MADGRAPH5_aMC@NLO [35] with the MLM prescription [36] for matching jets from the matrix element (ME) calculation to the parton shower description. Dedicated electroweak [37–42] and QCD (calculated with MADGRAPH5_aMC@NLO) NLO/LO K factors, parametrized as functions of the generated boson p_T , are applied to Z+jets and W+jets events. Other SM backgrounds include rare processes, such as $t\bar{t}$ +W and $t\bar{t}$ +Z, which are simulated based on the NLO ME calculations implemented in MADGRAPH5_aMC@NLO and the FxFx [43] prescription to merge multileg processes. Diboson processes (WW, WZ, ZZ, WH, ZH) are generated at NLO using either MADGRAPH5_aMC@NLO or POWHEG v2. All background samples are normalized using the most accurate cross section calculations available, which generally incorporate NLO or next-to-NLO (NNLO) precision.

The signal process is simulated at LO with the MADGRAPH5_aMC@NLO v2.4.2 event generator using a simplified model investigated within the LHC Dark Matter Forum [44]. In this model, the DM particles χ are assumed to be Dirac fermions and the mediators are spin-0 particles ϕ (a) that couple preferentially to third-generation SM quarks through scalar (pseudoscalar) couplings whose strengths are parametrized by the factor g_q . The coupling strength between the mediator and the DM particles is in turn given by the factor g_χ . This simplified model has a minimal set of four free parameters: $(m_\chi, m_{\phi/a}, g_\chi, g_q)$, and the benchmark scenarios assume $g_\chi = g_q = 1$ as per recommendations of the LHC Dark Matter Working Group [45]. In addition, in this search we focus on the $m_\chi = 1 \text{ GeV}$ benchmark, which is a convenient signal reference as the production cross section is almost independent of m_χ for on-shell mediators [44]. This simplified spin-0 model does not account for mixing between the ϕ scalar mediator and the SM Higgs boson, as discussed in Ref. [46]. Under these assumptions two distinct DM scenarios are possible: the associated production with a top quark pair ($t\bar{t}$ +DM) and the associated production with a single top quark (t/\bar{t} +DM). Cross sections for both signal processes are calculated at LO with MADGRAPH5_aMC@NLO v2.4.2, with one (zero) additional partons for $t\bar{t}$ +DM (t/\bar{t} +DM) events.

For all simulated samples, the initial-state partons are modeled with the NNPDF 3.0 [47] par-

ton distribution function (PDF) sets at LO or NLO in QCD to match the ME calculation. Generated events are interfaced with PYTHIA 8.205 [48] for parton showering and hadronization using the CUETP8M1 tune [49], except for simulated $t\bar{t}$ +jets events where the CUETP8M2 tune customized by CMS with an updated strong coupling α_s for initial-state radiation is employed [50]. All signal and background samples are processed using GEANT4 [51] to provide a full simulation of the CMS detector, including a simulation of the previously mentioned triggers. Correction factors are derived and applied to the simulated samples to match the trigger efficiencies measured in data. Additional corrections are applied to cover remaining residual differences between data and simulation that arise from the lepton identification and reconstruction efficiencies, as well as from b-tagged jet identification efficiencies.

4 Event selection

This search, similarly to a previous search for $t\bar{t}$ +DM events [16], defines several orthogonal signal regions (SRs) that are statistically combined in a simultaneous global fit of the p_T^{miss} spectrum. At the same time, various improvements are incorporated into this search to enhance the sensitivity to the t/\bar{t} +DM final state over that of previous analyses [16].

At the analysis level, jet candidates are required to have $p_T > 30$ GeV and are categorized as “central” if they lie within $|\eta| < 2.4$ and as “forward” if they are within $2.4 < |\eta| < 4.0$. The b-tagged jets identified by the CSVv2 algorithm are also required to have $p_T > 30$ GeV and in addition to lie within $|\eta| < 2.4$. Electrons and muons are selected with $p_T > 30$ GeV and $|\eta| < 2.1$. Events containing additional leptons with $p_T > 10$ GeV and $|\eta| < 2.1$ are vetoed. To ensure that candidate leptons are well-measured, identification requirements, based on hit information in the tracker and muon systems and on energy deposits in the calorimeters, are imposed. Leptons are further required to be isolated from hadronic activity, to reject leptons within jets that could arise, for example, from the decay of b quarks. A relative isolation quantity is defined as the scalar p_T sum of all PF candidates within a $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$ cone of radius 0.3 (0.4) centered around the electron (muon) candidate, where ϕ is the azimuthal angle in radians, divided by the lepton p_T [52, 53]. This relative isolation is required to be less than 0.059 (0.057) for electrons in the barrel (endcap) and less than 0.15 for muons.

Events are separated into orthogonal categories based on the number of b-tagged jets (n_b), with $n_b = 1$ or $n_b \geq 2$, and additional requirements on the number of forward jets are placed (0 or ≥ 1 forward jets) for the $n_b = 1$ category. The mentioned categorization in terms of forward jets allows a further enhancement of t/\bar{t} +DM t channel events. In fact, as shown in Fig. 1, this production mode leads to final states with one top quark and an additional jet, which tends to be in the forward region of the detector, while the additionally produced b quark is typically low in p_T and therefore is not reconstructed. The minimum requirements on the number of jets is also lowered, with respect to the previous searches, to enhance the sensitivity specifically to the t/\bar{t} +DM model. Control regions (CRs) enriched in the major background processes are included in the fit in order to improve the estimates of the background contributions.

Events are classified into two “channels”, based on the number of leptons in the final state from the top quark decay: the single-lepton SL channel, containing events with exactly one electron or muon with $p_T > 30$ GeV, and the all-hadronic AH channel, containing events with exactly zero leptons with $p_T > 10$ GeV. A set of discriminating variables is identified, as discussed in more detail in Sections 4.1 and 4.2 for the SL SRs and the AH SRs, respectively. The selection requirements on these variables are optimized simultaneously to increase the signal significance, using as a figure of merit the ratio between the expected number of signal and the square root

of the expected SM background events. The considered signal events are either t/\bar{t} +DM events for a region that contains exactly one b-tagged jet ($n_b = 1$) or $t\bar{t}$ +DM events for a region that contains two or more b-tagged jets ($n_b \geq 2$). The region with exactly one b-tagged jet is further divided into exactly zero or ≥ 1 forward jets.

4.1 Single-lepton signal regions

Events in the SL channel are required to contain ≥ 1 identified b-tagged jet, at least 2 jets with $p_T > 30$ GeV, and $p_T^{\text{miss}} > 160$ GeV. After this selection, the dominant backgrounds in the SL channel are from $t\bar{t}$ and W+jets processes. Other backgrounds include single top quark, Drell–Yan, and diboson production.

To further improve the sensitivity and to reduce the dominant background from single-lepton $t\bar{t}$ and W+jets processes, we impose a requirement on the transverse mass m_T , calculated as:

$$m_T = \sqrt{2p_T^{\text{miss}} p_T^\ell [1 - \cos(\Delta\phi)]}, \quad (3)$$

where p_T^ℓ is the transverse momentum of the lepton and $\Delta\phi$ is the opening angle between the lepton direction and the p_T^{miss} vector in the transverse plane. The m_T variable is constrained by kinematic properties to be less than the W boson mass for leptonic on-shell W decays in $t\bar{t}$ and W+jets events, while for signals, off-shell W decays, or for dileptonic decays of $t\bar{t}$, the m_T variable is expected to exceed the W mass because of the additional p_T^{miss} in the event. A requirement of $m_T > 160$ GeV therefore reduces the background from single-lepton events significantly and enhances the analysis sensitivity to the DM models.

After the m_T selection, the remaining $t\bar{t}$ background is primarily from events where both top quarks decay leptonically ($t\bar{t}(2\ell)$) and one lepton is not identified. This background can be further reduced by making use of the m_{T2}^W variable [54], which is defined as the minimal value of the mass of a particle assumed to be pair produced and to decay to a W boson and a b quark jet. The W bosons are assumed to be produced on-shell and to decay leptonically, where one of the two leptons is not detected. Based on the variable definition, in $t\bar{t}(2\ell)$ events the m_{T2}^W distribution has a kinematic end point at the top quark mass, assuming perfect detector response, while this is not the case for signal events where two additional DM particles are present. The calculation of m_{T2}^W requires two b-tagged jets from the decay of the top quarks, where one of these b-tagged jets comes from the same decay chain as the reconstructed lepton. If only one b-tagged jet is identified in the event, each of the first three (or two in three-jet events) leading non-b-tagged jets is considered as the second b-tagged jet in the calculation. The m_{T2}^W is then evaluated for all possible jet-lepton combinations and the minimum m_{T2}^W value is considered to discriminate between signal and background events. If two or more b-tagged jets are identified in the events, all b-tagged jets are considered and similarly all possible jet-lepton combinations are used to calculate m_{T2}^W values. The smallest of all the m_{T2}^W values is taken as the event discriminant.

In addition, jets and the \vec{p}_T^{miss} vector tend to be more separated in the transverse plane in signal events than in $t\bar{t}$ background processes. To improve the search sensitivity, the minimum opening angle $\min\Delta\phi(j_{1,2}, \vec{p}_T^{\text{miss}})$ in the transverse plane between the direction of each of the first two leading- p_T jets with $|\eta| < 2.4$ and the \vec{p}_T^{miss} vector is required to be greater than 1.2 radians.

The $t\bar{t}$ background is further reduced by requiring that the transverse mass m_T^b of the \vec{p}_T^{miss} vector and of a b-tagged jet is greater than 180 GeV, where m_T^b is defined similarly to Eq. (3) but considering a b-tagged jet instead of a lepton. In fact, for the remaining $t\bar{t}$ background m_T^b tends

to have values below or around the top quark mass if the b-tagged jet belongs to the top quark whose lepton is not identified. For the calculation we choose the b-tagged jet with the highest CSVv2 discriminant value, if there is more than one candidate.

A summary of the selection criteria for the SL SRs is shown in the first three columns of Table 1. Each region is identified by a unique name, where 0ℓ denotes exactly zero leptons, 1(2) b-tag represents exactly 1 (at least 2) b-tagged jet, and 0 FJ or 1 FJ denotes exactly zero or at least one forward jet.

Table 1: Final event selections for the SL and AH SRs. Electrons and muons are kept separate for the SL channel.

| | Single-lepton SRs | | | All-hadronic SRs | | |
|---|--------------------------|-------------------------|--------------------|--------------------------|--------------------------|--------------------|
| | 1 ℓ , 1 b-tag, 0 FJ | 1 ℓ , 1 b-tag, 1FJ | 1 ℓ , 2 b-tag | 0 ℓ , 1 b-tag, 0 FJ | 0 ℓ , 1 b-tag, 1 FJ | 0 ℓ , 2 b-tag |
| Forward jets | =0 | ≥ 1 | — | =0 | ≥ 1 | — |
| n_b | =1 | =1 | ≥ 2 | =1 | =1 | ≥ 2 |
| n_{lep} | =1 | =1 | =1 | =0 | =0 | =0 |
| $p_T(j_1)/H_T$ | — | — | — | — | — | <0.5 |
| n_{jet} | — | ≥ 2 | — | — | ≥ 3 | — |
| p_T^{miss} | — | >160 GeV | — | — | >250 GeV | — |
| m_T | — | >160 GeV | — | — | — | — |
| m_{T2}^W | — | >200 GeV | — | — | — | — |
| $\min\Delta\phi(j_{1,2}, \vec{p}_T^{miss})$ | — | >1.2 rad. | — | — | >1.0 rad. | — |
| m_T^b | — | >180 GeV | — | — | >180 GeV | — |

4.2 All-hadronic signal regions

Events categorized into the AH channel must contain at least 1 identified b-tagged jet and at least 3 jets with $p_T > 30$ GeV, $p_T^{miss} > 250$ GeV, and $\min\Delta\phi(j_{1,2}, \vec{p}_T^{miss})$ greater than 0.4 radians.

The dominant backgrounds after this selection arise from $t\bar{t}$, W+jets, and $Z \rightarrow \nu\nu$ processes. Other backgrounds include QCD multijet events, single top quark, Drell–Yan, and diboson production.

Semileptonic $t\bar{t}$ events populate this channel if the lepton in the final state is not identified. This $t\bar{t}(1\ell)$ background is reduced by applying the same m_T^b selection as introduced in the SL channel. To further reduce the $t\bar{t}(1\ell)$ background, together with that from $Z \rightarrow \nu\nu$ events, we make use of the $p_T(j_1)/H_T$ variable, which is defined as the ratio of the leading p_T jet in the event divided by the total hadronic transverse energy in the event, H_T , which is the scalar p_T sum of the jets with $p_T > 30$ GeV within $|\eta| < 2.4$. In the case of background, the distribution peaks at higher values with respect to $t\bar{t}$ +DM signal events. The t/\bar{t} +DM events, however, tend to exhibit a distribution similar to that of the background. Events in the $n_b \geq 2$ category are required to have $p_T(j_1)/H_T < 0.5$.

For QCD multijet events no intrinsic p_T^{miss} is expected. Therefore, events that pass our minimum p_T^{miss} selection contain mostly p_T^{miss} which arises from jet mismeasurements. For these events, the p_T^{miss} is often aligned with one of the leading jets. As a result, selecting events with $\min\Delta\phi(j_{1,2}, \vec{p}_T^{miss})$ values greater than 1 radian reduces the QCD multijet background further, to negligible contributions in the SR.

A summary of the selection criteria for the AH SRs is shown in the last three columns of Table 1. Each region is identified by a unique name, where 1 ℓ denotes exactly one muon or one electron, 1(2) b-tag represents exactly 1 (at least 2) b-tagged jet, and 0 FJ or 1 FJ denotes exactly zero or at least one forward jet.

4.3 Control regions

After events are categorized according to the selection presented in Table 1, the expected SM backgrounds in these different regions must be evaluated. In the SL SRs, the main backgrounds are dileptonic $t\bar{t}$ events, where one lepton is not identified, and W +jets events. For the AH regions the main backgrounds arise instead from single-lepton $t\bar{t}$ and W +jets events, where the lepton is not identified, and Z boson production, where the Z boson decays into two neutrinos and leads to a background with genuine p_T^{miss} .

In order to improve the estimation of these main backgrounds, methods based on control samples in data are used. In particular, CRs enhanced in the different background sources are used to derive correction factors as a function of the p_T^{miss} from the comparison of the p_T^{miss} distribution between the data and the simulation. These corrections are extracted and simultaneously propagated across the CRs and SRs for a given channel in the context of a global fit, as explained in more detail in Section 6. The residual background processes are modeled with simulation.

The background CRs for the SL and AH channels are designed to be statistically independent from the corresponding SRs.

4.3.1 Single-lepton control regions

The first set of CRs is defined to isolate dileptonic $t\bar{t}$ events by requiring exactly two leptons (1 electron and 1 muon, 2 electrons, or 2 muons), $n_{\text{jet}} \geq 2$, $n_b \geq 1$, and $p_T^{\text{miss}} > 160$ GeV. In order to statistically enhance these CRs the m_T , m_{T2}^W , and forward jet selections are removed.

The second set of CRs is designed to isolate W +jets events by requiring exactly one lepton (electron or muon), $n_{\text{jet}} \geq 2$, $n_b = 0$, $p_T^{\text{miss}} > 160$ GeV, and $m_T > 160$ GeV. The $n_b = 0$ requirement makes this CR orthogonal to the SL SR and allows the events in the m_T tail to be modeled without extrapolation from a lower- m_T region.

Both of these selections are summarized in the first two columns of Table 2.

Table 2: Control regions defined for the main backgrounds of the SL SRs (first two columns, $t\bar{t}(2\ell)$ and W +jets) and the AH SRs (last 3 columns, $t\bar{t}(1\ell)$, W +jets, and $Z \rightarrow \ell\ell$). Some selections applied in the SRs are removed in the corresponding CRs to increase the available statistics and are therefore not listed. The p_T^{miss} selection for the $Z \rightarrow \ell\ell$ CR refers to the hadronic recoil.

| | Single-lepton CRs | | All-hadronic CRs | | |
|--|----------------------|-----------------|----------------------|-----------------|------------------|
| | CR $t\bar{t}(2\ell)$ | CR $W(\ell\nu)$ | CR $t\bar{t}(1\ell)$ | CR $W(\ell\nu)$ | CR $Z(\ell\ell)$ |
| n_b | ≥ 1 | $= 0$ | ≥ 1 | $= 0$ | $= 0$ |
| n_{lep} | $= 2$ | $= 1$ | $= 1$ | $= 1$ | $= 2$ |
| n_{jet} | ≥ 2 | ≥ 2 | ≥ 3 | ≥ 3 | ≥ 3 |

4.3.2 All-hadronic control regions

For the AH SRs, three independent sets of CRs are defined. The first set of CRs is enhanced in single-lepton $t\bar{t}$ events selecting events with exactly one lepton (electron or muon), $n_{\text{jet}} \geq 3$, $n_b \geq 1$, $p_T^{\text{miss}} > 250$ GeV, and, in order to avoid overlap with the SL SRs, $m_T < 160$ GeV.

The second set of CRs is defined to enhance single-lepton W +jets events. Events are selected

with exactly one lepton (electron or muon), $n_{\text{jet}} \geq 3$, $n_{\text{b}} = 0$, $p_{\text{T}}^{\text{miss}} > 250 \text{ GeV}$, and in order to avoid overlap with the SL W+jets CR, $m_{\text{T}} < 160 \text{ GeV}$.

The third and last set of CRs are designed to model the background due to Z+jets production, where the Z boson decays into a pair of neutrinos ($Z \rightarrow \nu\nu$). Here we use the Z boson decays to an opposite-sign, same-flavor dilepton pair ($Z \rightarrow \ell\ell$), as proxy events to emulate the kinematic properties of the Z+jets process. Events are selected requiring 2 leptons, which have the same flavor (i.e., ee or $\mu\mu$), and opposite charge, and that satisfy a requirement on their invariant mass of $60 < m_{\ell\ell} < 120 \text{ GeV}$. Additionally, events must contain at least 3 jets, but events with b-tagged jets are vetoed ($n_{\text{b}} = 0$). In order to reproduce the p_{T} spectrum of $Z \rightarrow \nu\nu$ events, the two leptons are added to the $\vec{p}_{\text{T}}^{\text{miss}}$, referred to as hadronic recoil.

A summary of the different AH CRs can be found in the last three columns of Table 2.

5 Systematic uncertainties

Several sources of uncertainty are considered that affect either the simulation of the background processes or the underlying theoretical modeling. We distinguish between two types of uncertainties, ones that only affect the normalization of a process and others that additionally affect the shape of the $p_{\text{T}}^{\text{miss}}$ distribution. All of these uncertainties are included in the global simultaneous fit, described in detail later. The largest impacts on the final results stem from the uncertainties in the b tagging scale factors and the limited statistical precision of the dilepton $t\bar{t}$ CR, where the latter is the main determining factor for the contribution of $t\bar{t}$ events in the SL SRs.

The following sources of uncertainty correspond to constrained normalization nuisance parameters in the fit (unless specified, the source of uncertainty applies to all search channels):

- *Lepton reconstruction, selection, and trigger.* Scale factors are applied to the simulation in order to mimic the measured lepton reconstruction and selection efficiencies in data. The measured uncertainties in these scale factors are of the order of 2.2% per electron and 1% per muon, and are p_{T} and η dependent [52, 53]. The effect of these uncertainties is found to be independent of the $p_{\text{T}}^{\text{miss}}$ spectrum.
- *$p_{\text{T}}^{\text{miss}}$ trigger.* At values of $p_{\text{T}}^{\text{miss}} > 250 \text{ GeV}$ the applied triggers are almost fully efficient; a normalization uncertainty of 2% is assigned. This uncertainty is only applied in the AH channel.
- *b tagging efficiency scale factors.* The b tagging and light-flavor mistag efficiencies scale factors and the respective uncertainties are measured in independent control samples [30], and propagated to the analysis. In the range of $p_{\text{T}}^{\text{miss}}$ considered, these scale factor uncertainties do not alter the shape of the $p_{\text{T}}^{\text{miss}}$ distribution.
- *Forward jets.* Inclusive CRs in terms of forward jet multiplicity are considered to constrain the major background in the 0 and ≥ 1 forward jets SRs. The impact of this extrapolation in forward jets multiplicity on the background estimation is evaluated and assigned as additional systematic uncertainty. The extrapolation effect is evaluated by splitting each CR into a 0f and 1f category, and a systematic uncertainty is assigned based on the ratio of the correction factors, where each correction factor is the ratio of the data to the simulation in its category. This uncertainty ranges from approximately 2% (W+jets AH) to about 7% ($t\bar{t}$ SL).
- *Pileup modeling.* Systematic uncertainties due to pileup modeling are taken into account by varying the total inelastic cross section used to calculate pileup distribu-

tions in simulation by $\pm 4.6\%$ [55].

- *Luminosity.* An uncertainty of 2.5% is taken on the integrated luminosity of the data sample [56].
- *QCD multijet background normalization.* An uncertainty of 100% in the normalization is considered for QCD processes to cover effects in the kinematic tails that may not be well-modeled by the simulation. This has little overall impact on the final result, since the contribution from QCD multijet events is reduced to a negligible amount in this analysis.
- *Single top quark background normalization.* An uncertainty of 20% in the normalization is considered for single top quark processes, accounting for the uncertainty in the PDF and the effects from varying the factorization and renormalization scale parameters.
- *Uncertainty related to ECAL mistiming.* Partial mistiming of signals in the forward regions of the ECAL endcaps led to a minor reduction in trigger efficiency. To cover this effect, an additional uncertainty is applied on the signal acceptances of up to 10% in the forward jet categories. A potential effect on the background extrapolation into regions with forward jets is already taken into account by a dedicated systematic uncertainty.

The following sources of uncertainty affect the shape of the p_T^{miss} distribution, as well as the normalization of the various backgrounds and the signal, and are applied to all search channels:

- *Jet energy scale.* Reconstructed jet four-momenta in the simulation are varied according to the uncertainty in the jet energy scale. Jet energy scale uncertainties are coherently propagated to all observables, including p_T^{miss} [57].
- *PDF uncertainties.* Uncertainties due to the choice of PDF are estimated by reweighting the samples with the NNPDF3.0 [47] replicas [58] and are applied to all backgrounds except for the single top quark, as these uncertainties are covered by the associated background normalization uncertainty.
- *W/Z+heavy-flavor fraction.* The uncertainty in the fraction of W/Z+heavy-flavor (HF) jets in W+jets and Z+jets event is taken into account. The relative contribution of W+HF and Z+HF are allowed to vary within 20% [59–62].
- *Electroweak and QCD K factors.* Uncertainties in the NLO/LO K factors calculated for W+jets and Z+jets processes are considered. These uncertainties account for missing higher-order corrections. For QCD, this comes from variations due to factorization and renormalization scales. For electroweak processes, an estimate of the size of the missing higher-order corrections is obtained by taking the difference between applying and not applying the NLO/LO electroweak K factors.
- *Top quark p_T reweighting.* Differential measurements of the top quark p_T spectrum in top quark pair production events [34] show that the measured p_T spectrum is softer than in simulation. In order to improve the description of top quark pair events, simulated samples are reweighted to match the measurements. An associated systematic uncertainty is estimated by taking the difference between applying and not applying the reweighting.
- *Factorization and renormalization scales.* The uncertainties in the choice of the factorization and renormalization scale parameters are taken into account for the $t\bar{t}$, $t\bar{t}+V$, and diboson processes by applying a set of weights that represent a change of these scales by a factor of 2 or 0.5.

- *Simulation sample size.* Uncertainties due to the limited size of the simulated signal and background samples are included by allowing each bin of the distributions used in the signal extraction to fluctuate independently according to the statistical uncertainties in simulation, following Ref. [63].

6 Signal extraction

As previously discussed, the potential DM signal is expected to have the signature of $t\bar{t}$ or single top quark events with additional p_T^{miss} , therefore leading to an excess of events above the SM prediction in the p_T^{miss} spectrum. The DM signal is extracted from a simultaneous fit to the binned p_T^{miss} distribution in the various SRs and CRs, including all previously mentioned uncertainties. This global fit is performed as a binned maximum likelihood fit employing the ROOSTATS statistical package [64]. The main SM backgrounds were discussed previously in Section 4, and are dileptonic $t\bar{t}$ +jets and W +jets events for the SL SRs, and $Z \rightarrow \nu\nu$, single-lepton $t\bar{t}$ +jets, and W +jets events for the AH SRs.

The effect of the systematic uncertainties in the shape and normalization of the p_T^{miss} spectrum, as discussed in the previous section, is taken into account by introducing nuisance parameters, which are constrained by the magnitude of the corresponding source of uncertainty. Uncertainties that affect normalization only are modeled using nuisances with log-normal probability densities. These parameters are treated as correlated between p_T^{miss} bins and between the different CRs and SRs within each channel. The sources common between SL and AH SRs and CRs are correlated across channels.

To improve the estimation of the main backgrounds, an unconstrained multiplicative parameter is assigned separately to each background for each bin of the p_T^{miss} spectrum. These multiplicative parameters scale the normalization of the associated background process simultaneously in the SRs and CRs for a given channel. For example, in a given p_T^{miss} bin of the SL selection, there is one multiplicative parameter for $t\bar{t}$ that links the $t\bar{t}$ background in the $t\bar{t}$ enhanced 2ℓ CR, the W +jets enhanced 1ℓ CR, and the SR. Therefore, the effect of contributions of the same background process in the different CRs is also taken into account. Additionally, potential contributions from the DM signals are included for all CRs and SRs, and scaled by a signal strength modifier $\mu = \sigma/\sigma_{\text{th}}$, i.e., the ratio between the measured and theoretical cross sections. Regions containing leptons (electrons and muons) are separated by lepton flavor.

The simultaneous fit to the binned p_T^{miss} distribution is performed combining the SL and AH regions. The values for the background multiplicative factors extracted from the fit are on average close to one, with a root-mean-square deviation that ranges from 5% to 21%, depending on the background processes and on the category considered (SL or AH). The post-fit distributions assuming the absence from the DM signal (i.e., the background only fit) are shown in Figs. 2 and 3 (4 and 5) for the SL and AH CRs (SRs), respectively. The SRs, both for the SL and AH channels, are divided into: 1 b-tagged jet and 0 forward jets, 1 b-tagged jet and ≥ 1 forward jets, and ≥ 2 b-tagged jets. The plots also contain the pre-fit distributions, represented by the dashed magenta line. The statistical and systematic uncertainties in the prediction are represented by hatched uncertainty bands, while the lower panels show the ratio of data and the post-fit prediction, and the bottom panels show the difference between the observed data events and the post-fit total background, divided by the full statistical and systematic uncertainty.

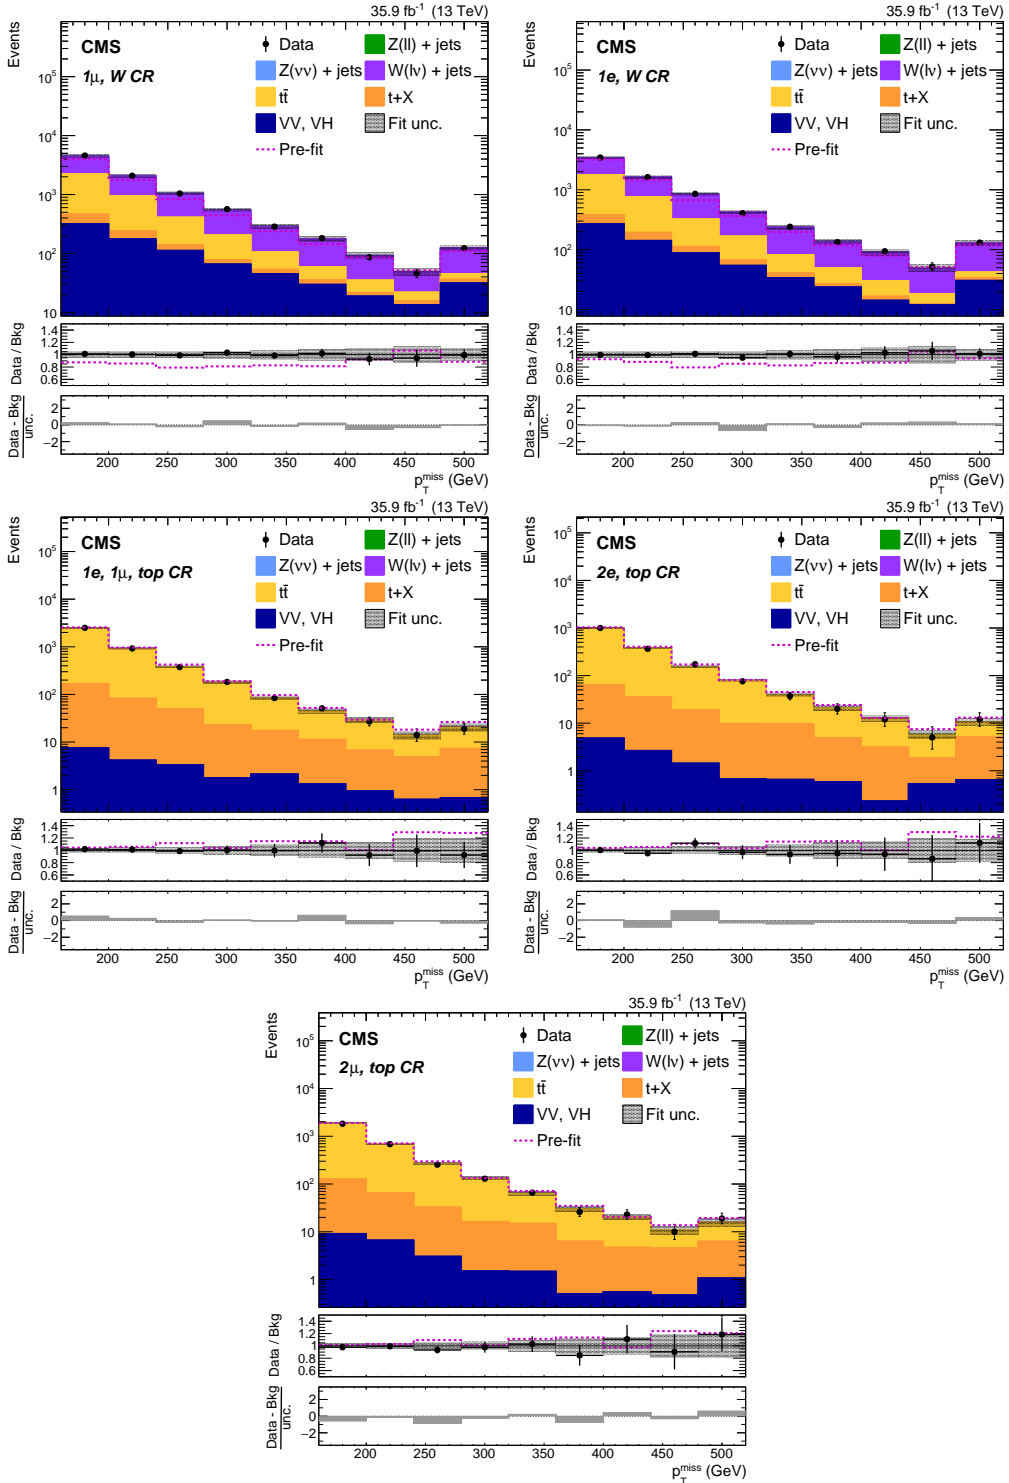

Figure 2: Background-only post-fit p_T^{miss} distributions for the CRs of the SL selection. The total theory signal ($t/\bar{t}+\text{DM}$ and $t\bar{t}+\text{DM}$ summed together) is negligible and therefore is not shown. The last bin contains overflow events. The dashed magenta lines show the total pre-fit background expectation in the upper panels, and the ratio of pre-fit total background to post-fit total background in the middle panels. The lower panels show the difference between observed and post-fit total background divided by the full statistical and systematic uncertainties.

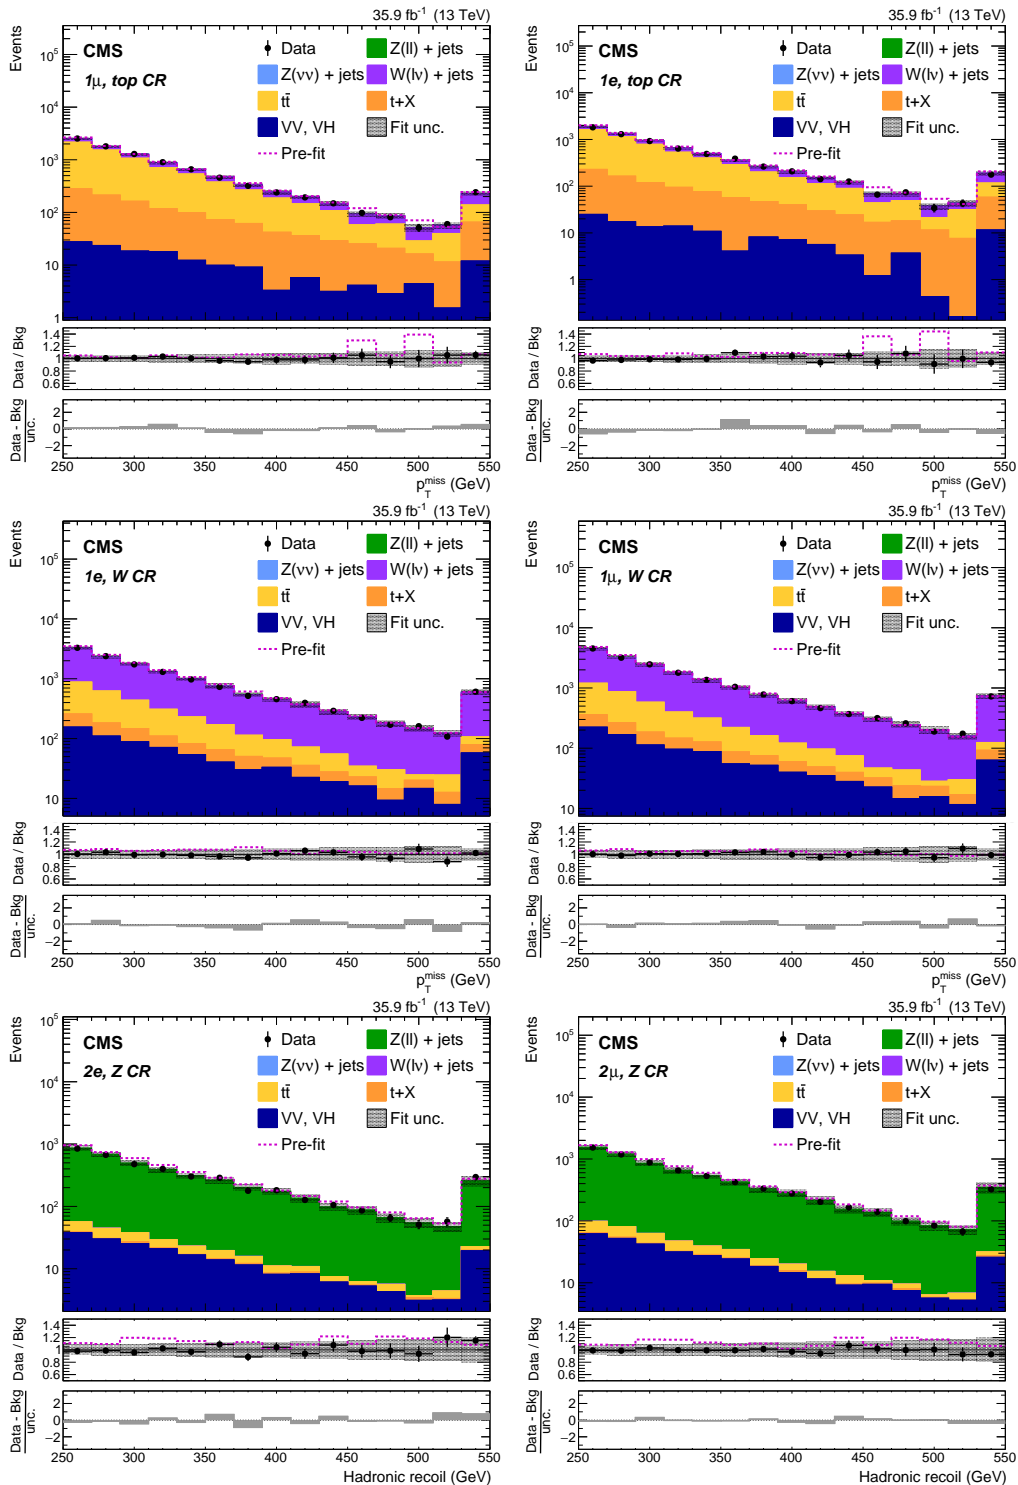

Figure 3: Background-only post-fit p_T^{miss} distributions for the CRs of the AH selection. The total theory signal ($t/\bar{t} + \text{DM}$ and $t\bar{t} + \text{DM}$ summed together) is negligible and therefore is not shown. The last bin contains overflow events. The dashed magenta lines show the total pre-fit background expectation in the upper panels, and the ratio of pre-fit total background to post-fit total background in the middle panels. The lower panels show the difference between observed and post-fit total background divided by the full statistical and systematic uncertainties.

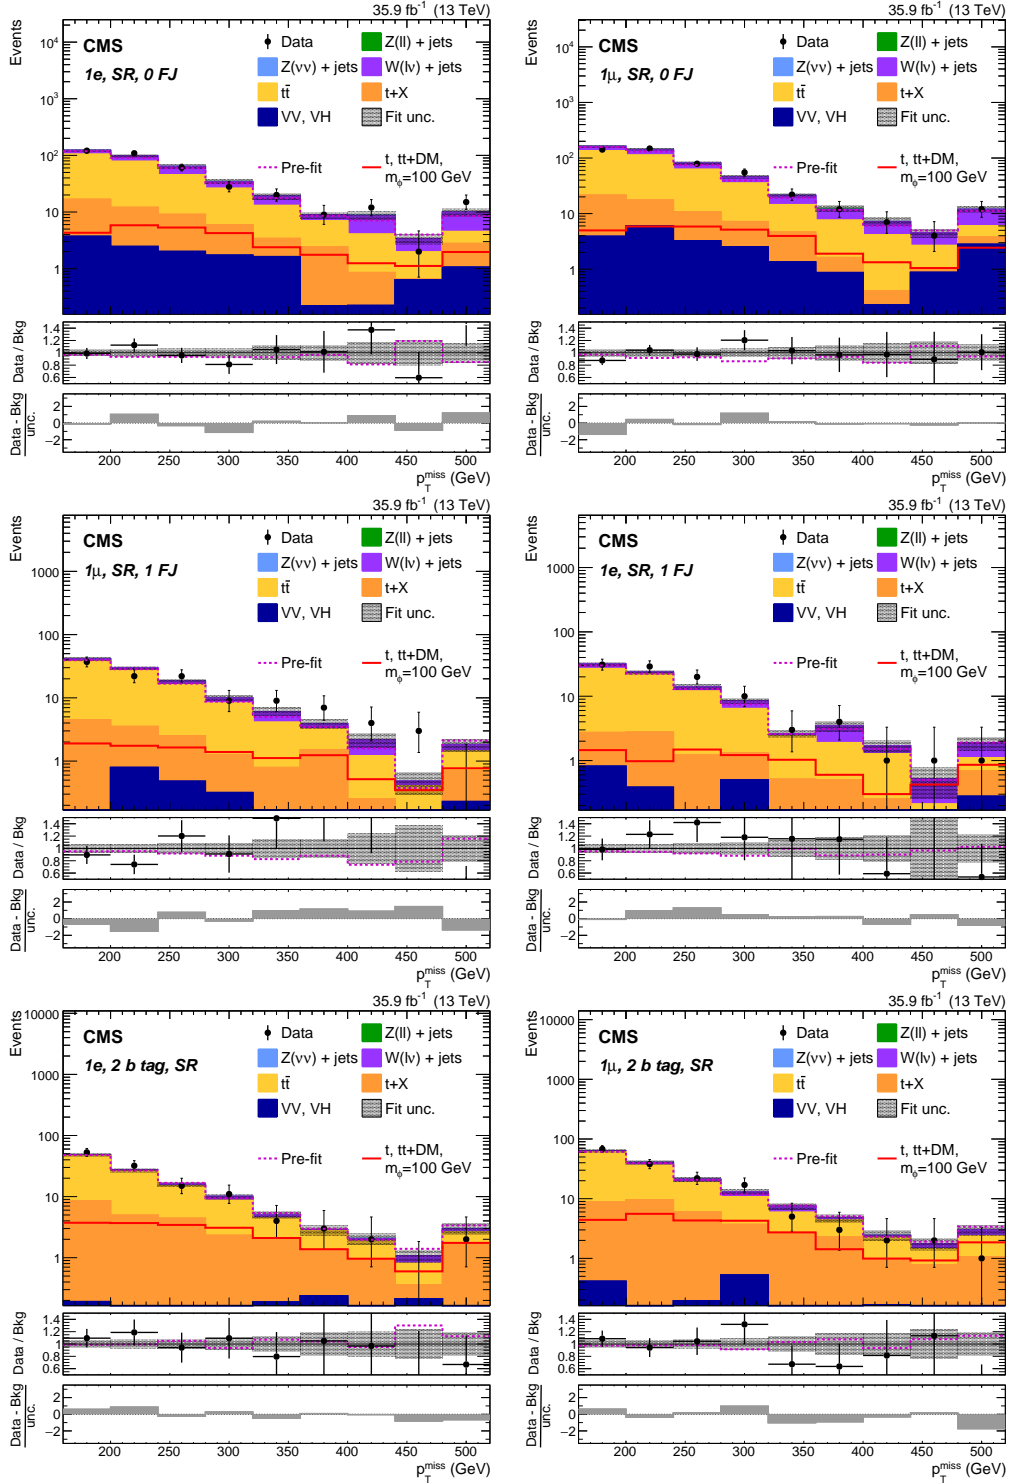

Figure 4: Background-only post-fit p_T^{miss} distributions for the SRs of the SL selection. The total theory signal ($t/\bar{t}+\text{DM}$ and $\bar{t}+\text{DM}$ summed together) is presented by the red solid lines for a scalar mediator mass of 100 GeV. The last bin contains overflow events. The dashed magenta lines show the total pre-fit background expectation in the upper panels, and the ratio of pre-fit total background to post-fit total background in the middle panels. The lower panels show the difference between observed and post-fit total background divided by the full statistical and systematic uncertainties.

Figure 5: Background-only post-fit p_T^{miss} distributions for the SRs of the AH selection. The total theory signal ($t/\bar{t}+\text{DM}$ and $\bar{t}\bar{t}+\text{DM}$ summed together) is presented by the red solid lines for a scalar mediator mass of 100 GeV. The last bin contains overflow events. The dashed magenta lines show the total pre-fit background expectation in the upper panels, and the ratio of pre-fit total background to post-fit total background in the middle panels. The lower panels show the difference between observed and post-fit total background divided by the full statistical and systematic uncertainties.

7 Results

Overall, data are found to be in agreement with the expected SM background in the SRs. Upper limits at 95% confidence level (CL) are computed on the ratio between the measured and theoretical cross sections μ , which is calculated with respect to the expected number of events for a scalar or pseudoscalar mediator and either the $t/\bar{t}+\text{DM}$ or $\bar{t}\bar{t}+\text{DM}$ production modes separately, or summed together, where the results are referred to here as $t, \bar{t}\bar{t}+\text{DM}$. The theoretical cross sections for both signal models are obtained at LO. The limits are calculated using a modified frequentist approach with a test statistic based on the profile likelihood in the asymptotic approximation and the CL_s criterion [65–67]. We test different mediator mass scenarios with $m_\chi = 1 \text{ GeV}$ and $g_q = g_\chi = 1$ and the results are shown in Fig. 6 for scalar (left) and pseudoscalar (right) models. The expected limit for the $t/\bar{t}+\text{DM}$ signal alone is depicted by the blue dash-dotted line, while the expected $\bar{t}\bar{t}+\text{DM}$ limit alone is given by the red dash-dotted line. The observed limit on the sum of both signals is represented by the black solid line, while its expected value is shown by the black dashed line with the 68 and 95% CL uncertainty bands in green and yellow, respectively.

For masses of the mediator particle below 200 GeV for the scalar model and below 300 GeV for the pseudoscalar model, the leading contribution to the sensitivity of the analysis stems from $\bar{t}\bar{t}+\text{DM}$. This behavior is mostly driven by the larger cross section for the $\bar{t}\bar{t}+\text{DM}$ process when compared to the sum of the production processes for $t/\bar{t}+\text{DM}$. However, the $t/\bar{t}+\text{DM}$ cross section drops less rapidly as a function of mediator particle mass in comparison to the $\bar{t}\bar{t}+\text{DM}$ mode. Additionally, the p_T^{miss} spectrum for a given mediator mass leans towards higher values for the $t/\bar{t}+\text{DM}$ signal model when compared to the $\bar{t}\bar{t}+\text{DM}$ model. These two features, together with the analysis specifically designed for both DM production modes and the statistical combination of the different SRs, lead up to a factor of two improvement at high mediator masses on the limits when compared to previous results [16]. In particular, the ≥ 1 forward jet category, which is specifically designed to enhance $t/\bar{t}+\text{DM}$ t channel events, improves the final results up to 14%.

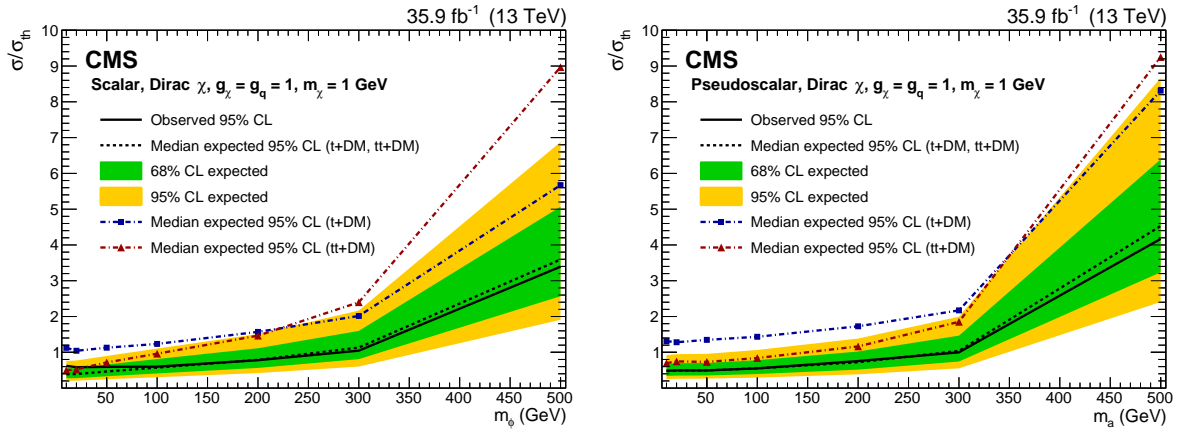

Figure 6: The expected and observed 95% CL limits on the DM production cross sections, relative to the theory predictions, shown for the scalar (left) and pseudoscalar (right) models. The expected limit for the $t/\bar{t}+\text{DM}$ signal alone is depicted by the blue dash-dotted line, while the $\bar{t}\bar{t}+\text{DM}$ limit alone is given by the red dash-dotted line. The observed limit on the sum of both signals is shown by the black solid line, while the expected value is shown by the black dashed line with the 68 and 95% CL uncertainty bands in green and yellow, respectively.

Table 3 represents the final combined limits (SL + AH) for the $t/\bar{t}+\text{DM}$ and $\bar{t}\bar{t}+\text{DM}$ processes separately, and for the sum of the two processes.

Overall, we exclude mediator masses below 290 and 300 GeV for the scalar and pseudoscalar hypotheses, respectively.

Table 3: Upper limits at 95% CL on the cross section ratio with respect to the expected DM signal for different scalar (ϕ) or pseudoscalar (a) mediator masses, $m_\chi = 1$ GeV, and $g_\chi = g_q = 1$ for the combination of SL and AH signal regions. The median expected value and its 68 and 95% confidence intervals (CIs) are given.

8 Summary

The first search at the LHC for dark matter (DM) produced in association with a single top quark or a top quark pair in interactions mediated by a neutral scalar or pseudoscalar particle in proton-proton collisions at a center-of-mass energy of 13 TeV has been presented. The data correspond to an integrated luminosity of 35.9 fb^{-1} recorded by the CMS experiment in 2016. No significant deviations with respect to standard model predictions are observed and the results are interpreted in the context of a simplified model in which a scalar or pseudoscalar mediator particle couples to the top quark and subsequently decays into two DM particles.

Scalar and pseudoscalar mediator masses below 290 and 300 GeV are excluded at 95% confidence level assuming a DM particle mass of 1 GeV and mediator couplings to fermions and DM particles equal to unity. This analysis provides the most stringent limits derived at the LHC for these new spin-0 mediator particles.

Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centres and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMBWF and FWF (Austria); FNRS

and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); SENESCYT (Ecuador); MoER, ERC IUT, and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); NKfIA (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MOS (Montenegro); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS, RFBR, and NRC KI (Russia); MESTD (Serbia); SEIDI, CPAN, PCTI, and FEDER (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR, and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

Individuals have received support from the Marie-Curie programme and the European Research Council and Horizon 2020 Grant, contract No. 675440 (European Union); the Leventis Foundation; the A.P. Sloan Foundation; the Alexander von Humboldt Foundation; the Belgian Federal Science Policy Office; the Fonds pour la Formation à la Recherche dans l'Industrie et dans l'Agriculture (FRIA-Belgium); the Agentschap voor Innovatie door Wetenschap en Technologie (IWT-Belgium); the F.R.S.-FNRS and FWO (Belgium) under the "Excellence of Science – EOS" – be.h project n. 30820817; the Ministry of Education, Youth and Sports (MEYS) of the Czech Republic; the Lendület ("Momentum") Programme and the János Bolyai Research Scholarship of the Hungarian Academy of Sciences, the New National Excellence Program ÚNKP, the NKfIA research grants 123842, 123959, 124845, 124850, and 125105 (Hungary); the Council of Science and Industrial Research, India; the HOMING PLUS programme of the Foundation for Polish Science, cofinanced from European Union, Regional Development Fund, the Mobility Plus programme of the Ministry of Science and Higher Education, the National Science Center (Poland), contracts Harmonia 2014/14/M/ST2/00428, Opus 2014/13/B/ST2/02543, 2014/15/B/ST2/03998, and 2015/19/B/ST2/02861, Sonata-bis 2012/07/E/ST2/01406; the National Priorities Research Program by Qatar National Research Fund; the Programa Estatal de Fomento de la Investigación Científica y Técnica de Excelencia María de Maeztu, grant MDM-2015-0509 and the Programa Severo Ochoa del Principado de Asturias; the Thalís and Aristeia programmes cofinanced by EU-ESF and the Greek NSRF; the Rachadapisek Sompot Fund for Postdoctoral Fellowship, Chulalongkorn University and the Chulalongkorn Academic into Its 2nd Century Project Advancement Project (Thailand); the Welch Foundation, contract C-1845; and the Weston Havens Foundation (USA).

†: Deceased

1: Also at Vienna University of Technology, Vienna, Austria

2: Also at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France

3: Also at Universidade Estadual de Campinas, Campinas, Brazil

4: Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil

5: Also at Université Libre de Bruxelles, Bruxelles, Belgium

6: Also at University of Chinese Academy of Sciences, Beijing, China

7: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia

8: Also at Joint Institute for Nuclear Research, Dubna, Russia

9: Now at British University in Egypt, Cairo, Egypt

10: Now at Cairo University, Cairo, Egypt

11: Now at Ain Shams University, Cairo, Egypt

12: Also at Department of Physics, King Abdulaziz University, Jeddah, Saudi Arabia

13: Also at Université de Haute Alsace, Mulhouse, France

14: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia

15: Also at Ilia State University, Tbilisi, Georgia

16: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland

17: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany

18: Also at University of Hamburg, Hamburg, Germany

19: Also at Brandenburg University of Technology, Cottbus, Germany

20: Also at Institute of Physics, University of Debrecen, Debrecen, Hungary

21: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary

22: Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary

- 23: Also at Indian Institute of Technology Bhubaneswar, Bhubaneswar, India
- 24: Also at Institute of Physics, Bhubaneswar, India
- 25: Also at Shoolini University, Solan, India
- 26: Also at University of Visva-Bharati, Santiniketan, India
- 27: Also at Isfahan University of Technology, Isfahan, Iran
- 28: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
- 29: Also at Università degli Studi di Siena, Siena, Italy
- 30: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy
- 31: Also at Kyunghee University, Seoul, Korea
- 32: Also at International Islamic University of Malaysia, Kuala Lumpur, Malaysia
- 33: Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia
- 34: Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico
- 35: Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland
- 36: Also at Institute for Nuclear Research, Moscow, Russia
- 37: Now at National Research Nuclear University 'Moscow Engineering Physics Institute' (MEPhI), Moscow, Russia
- 38: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
- 39: Also at University of Florida, Gainesville, USA
- 40: Also at P.N. Lebedev Physical Institute, Moscow, Russia
- 41: Also at California Institute of Technology, Pasadena, USA
- 42: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia
- 43: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
- 44: Also at INFN Sezione di Pavia ^a, Università di Pavia ^b, Pavia, Italy
- 45: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
- 46: Also at National and Kapodistrian University of Athens, Athens, Greece
- 47: Also at Riga Technical University, Riga, Latvia
- 48: Also at Universität Zürich, Zurich, Switzerland
- 49: Also at Stefan Meyer Institute for Subatomic Physics (SMI), Vienna, Austria
- 50: Also at Adiyaman University, Adiyaman, Turkey
- 51: Also at Istanbul Aydin University, Istanbul, Turkey
- 52: Also at Mersin University, Mersin, Turkey
- 53: Also at Piri Reis University, Istanbul, Turkey
- 54: Also at Gaziosmanpasa University, Tokat, Turkey
- 55: Also at Ozyegin University, Istanbul, Turkey
- 56: Also at Izmir Institute of Technology, Izmir, Turkey
- 57: Also at Marmara University, Istanbul, Turkey
- 58: Also at Kafkas University, Kars, Turkey
- 59: Also at Istanbul University, Faculty of Science, Istanbul, Turkey
- 60: Also at Istanbul Bilgi University, Istanbul, Turkey
- 61: Also at Hacettepe University, Ankara, Turkey
- 62: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
- 63: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
- 64: Also at Monash University, Faculty of Science, Clayton, Australia
- 65: Also at Bethel University, St. Paul, USA
- 66: Also at Karamanoğlu Mehmetbey University, Karaman, Turkey
- 67: Also at Utah Valley University, Orem, USA

68: Also at Purdue University, West Lafayette, USA

69: Also at Beykent University, Istanbul, Turkey

70: Also at Bingol University, Bingol, Turkey

71: Also at Sinop University, Sinop, Turkey

72: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey

73: Also at Texas A&M University at Qatar, Doha, Qatar

74: Also at Kyungpook National University, Daegu, Korea
