Observation of electroweak production of two jets and a Z-boson pair with the ATLAS detector at the LHC

The ATLAS Collaboration

Electroweak symmetry breaking explains the origin of the masses of elementary particles via their interactions with the Higgs field. Besides the measurements of the Higgs boson properties, the study of the scattering of massive vector bosons (with spin one) at the Large Hadron Collider allows to probe the nature of electroweak symmetry breaking with an unprecedented sensitivity. Among all processes related to vector-boson scattering, the electroweak production of two jets and a Z-boson pair is a rare and important one. This article reports on the first observation of this process using proton–proton collision data corresponding to an integrated luminosity of 139 fb^{-1} recorded at a centre-of-mass energy of 13 TeV by the ATLAS detector. Two different final states originating from the decays of the Z-boson pair, one containing four charged leptons and the other containing two charged leptons and two neutrinos, are considered. The hypothesis of no electroweak production is rejected with a statistical significance of 5.5σ , and the measured cross-section for electroweak production is consistent with the Standard Model prediction. In addition, cross-sections for inclusive production of a Z-boson pair and two jets are reported for the two final states.

1 Introduction

Electroweak symmetry breaking (EWSB) plays a central role in the Standard Model (SM) of particle physics, as it explains the origin of elementary particle masses via the interactions of each particle with the Higgs field. Following the discovery of the Higgs boson [1, 2], the scrutiny of EWSB has become a primary focus of research at the Large Hadron Collider (LHC). In addition to direct measurements of the Higgs boson’s properties, the scattering of two massive vector bosons (VBS) offers another key avenue to probe the EWSB mechanism [3–5]. As a result of the delicate configuration of quantum field interactions for the SM VBS processes [3], the presence of the Higgs boson is predicted to exactly cancel out the otherwise diverging VBS amplitudes at high energies and prevent unitarity violation at the TeV scale. However, many possible extensions to the SM, such as Supersymmetry [6], Little Higgs [7], or Composite Higgs [8] models, offer alternative EWSB mechanisms that would manifest as deviations from the SM VBS production cross-sections at high energies. The study of the high-energy behaviour of VBS is therefore crucial in the attempt to quantify the exact nature of EWSB. Moreover, VBS offers a sensitive means to search for new phenomena related to anomalies in the weak-boson self-interactions [9], which are precisely predicted by the gauge theory in the SM.

The LHC provides an unprecedented opportunity to study the VBS process in proton–proton (pp) collisions, due to the high collision energies and large luminosity. At the LHC, VBS occurs when two vector bosons (V) are radiated from the initial-state quarks in the colliding protons, and then scatter into another pair of vector bosons in the final state. The detector signature of VBS includes the decay products of the pair of outgoing bosons and a pair of hadronic jets (j), which originate from the deflection of the initial-state quarks that radiated the weak bosons. The most promising channel to measure VBS is the purely electroweak (EW) production of $VVjj$ (EW $VVjj$) in pp collisions, in which the contributions from the non-VBS processes (such as triboson production) could be sufficiently suppressed with a proper choice of kinematic selections. Thus far, the EW $W^\pm W^\pm jj$ and $WZjj$ processes have been observed using LHC Run 2 data [10–12], and no significant deviations from the SM predictions have been found. The CMS Collaboration has searched for EW $ZZjj$ production using 36.1 fb^{-1} of 13 TeV pp collision data, which was too small a sample to claim evidence [13] of this rarest EW $VVjj$ process. Despite the small rate, EW $ZZjj$ production is of significant interest, due to the low background and the unique feature of a fully reconstructed final state when both of the Z bosons decay into charged leptons. The complete reconstruction of the final-state bosons provides maximal information in which the properties of the VBS process that are sensitive to EWSB can be probed. Furthermore, of all the measurements to date, VBS ZZ production is uniquely sensitive to the possible anomalous interaction between four Z bosons. This is forbidden at tree-level in the SM and the study of EW $ZZjj$ production is therefore a direct test of an important prediction of the electroweak theory. Finally, precision measurements of high-mass VBS ZZ production also allow an almost model-independent measurement of the Higgs boson width. The Higgs width is precisely predicted by the SM and is sensitive to new phenomena in the Higgs sector. However, the current methods to extract the Higgs width (using the gluon–gluon fusion production mechanism) are known to fail for certain types of new phenomena and the use of the VBS production mechanism was proposed in order to alleviate this problem [14].

This article reports the first observation of EW $ZZjj$ production using the complete set of 13 TeV pp collision data recorded by the ATLAS experiment during the LHC Run 2, as well as a measurement of the cross-sections of the inclusive (EW and non-EW) $ZZjj$ processes. The search is performed in two final states where both Z bosons decay leptonically: in final states with either four charged leptons and two jets ($\ell\ell\ell\ell jj$), or two charged leptons, two neutrinos and two jets ($\ell\ell\nu\nu jj$). The definition of the signal

region is optimised to suppress the reducible backgrounds coming from processes with different final states. Multivariate discriminants (MDs) are used to further separate the EW signal from the remaining backgrounds, including both the reducible ones and the irreducible non-EW $ZZjj$ process, which contains two strong interactions at the lowest order in perturbation theory and is referred to as QCD $VVjj$ production. Figure 1 depicts the typical diagrams for both the EW VBS and QCD $ZZjj$ processes. These MDs exploit the characteristics of VBS production, such as a large separation in rapidity between the two jets ($\Delta y(jj)$) as well as a significant invariant mass of the jet pair (m_{jj}). The production of $ZZjj$ in which one or both Z bosons decay into electrons or muons via τ -leptons is considered as signal, but it makes a negligible contribution to the selected event sample.

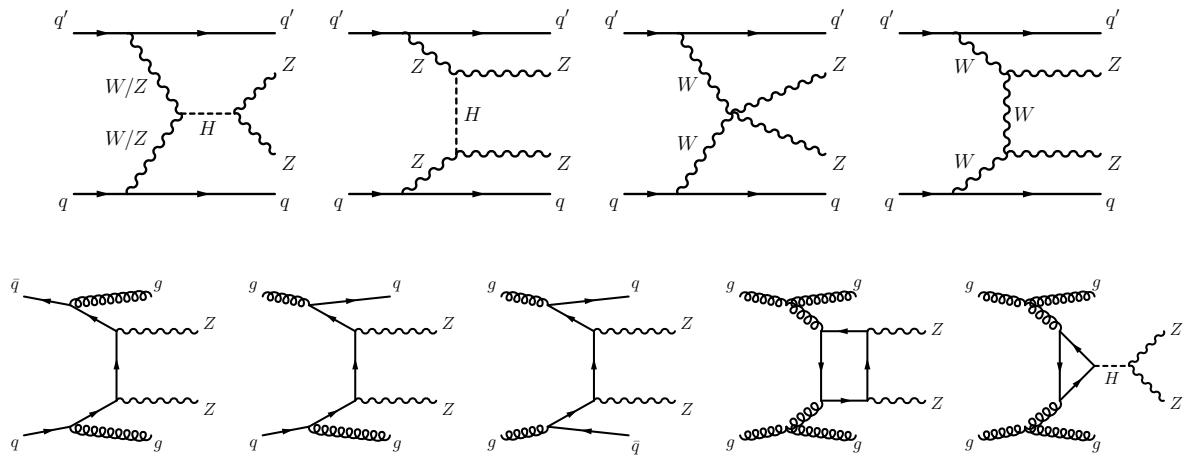

Figure 1: Typical diagrams for the production of $ZZjj$, including the relevant EW VBS diagrams (first row) and QCD diagrams (second row).

2 Experimental apparatus

The ATLAS experiment [15–17] at the LHC uses a multipurpose particle detector with a forward–backward symmetric cylindrical geometry and a near 4π coverage in solid angle. ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the centre of the detector and the z -axis along the beam pipe. The x -axis points from the IP to the centre of the LHC ring, and the y -axis points upwards. Cylindrical coordinates (r, ϕ) are used in the transverse plane, ϕ being the azimuthal angle around the z -axis. The pseudorapidity is defined in terms of the polar angle θ as $\eta = -\ln \tan(\theta/2)$. The angular distance between two physics objects is measured in units of $\Delta R \equiv \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$. The ATLAS detector consists of an inner tracking detector (ID) surrounded by a thin superconducting solenoid providing a 2 T axial magnetic field, electromagnetic (EM) and hadron calorimeters, and a muon spectrometer (MS). The ID covers the pseudorapidity range $|\eta| < 2.5$. It consists of silicon pixel, silicon microstrip, and transition radiation tracking detectors. Lead/liquid-argon (LAr) sampling calorimeters provide EM energy measurements with high granularity. A steel/scintillator-tile hadron calorimeter covers the central pseudorapidity range ($|\eta| < 1.7$). The endcap and forward regions are instrumented with LAr calorimeters for EM and hadronic energy measurements up to $|\eta| = 4.9$. The MS surrounds the calorimeters and is based on three large air-core toroidal superconducting magnets with eight coils each. The field integral

of the toroids ranges between 2.0 and 6.0 Tm across most of the detector. The MS includes a system of precision tracking chambers and fast detectors for triggering. A two-level trigger system [18] is used to select events for offline analysis. The first-level trigger is implemented in hardware and uses a subset of the detector information. This is followed by the software-based high-level trigger, which reduces the event selection rate to about 1 kHz.

3 Data and simulation

The data for this analysis were recorded using single-lepton and multi-lepton triggers, corresponding to an integrated luminosity of 139 fb^{-1} . The overall trigger efficiency for the inclusive $ZZjj$ events selected for this analysis ranges from 95% to 99%.

The EW $ZZjj$ production was modelled using the `MADGRAPH5_aMC@NLO` 2.6.1 event generator [19] with matrix elements (ME) calculated at leading order (LO) in perturbative QCD (pQCD) and with the NNPDF2.3LO [20] parton distribution functions (PDF). The QCD $ZZjj$ production was modelled using `SHERPA` 2.2.2 [21] with the NNPDF3.0NNLO [22] PDF, where events with up to one (three) outgoing partons were generated at NLO (LO) in pQCD. The production of $ZZjj$ from the gluon–gluon initial state with a four-fermion loop or with the exchange of a Higgs boson was generated separately. This process, referred to as the $ggZZjj$ process, was modelled using `SHERPA` 2.2.2 and `GG2VV` [23] in the $\ell\ell\ell\ell jj$ and $\ell\ell vv jj$ channels, respectively, and normalised to a calculation accurate to NLO in perturbative QCD. The leptonic decays of Z bosons are included in the simulation. Interference between EW and QCD $ZZjj$ was modelled with `MADGRAPH5_aMC@NLO` 2.6.1 calculated at LO and is treated as systematic on the predicted EW process. The effect is far smaller than the statistical uncertainty from data.

The production of $WWjj$ and $WZjj$ with the subsequent leptonic decays of vector bosons were modelled with `SHERPA` 2.2.2. Diboson processes with the subsequent semileptonic decays were modelled using `POWHEG-Box v2` [24]. Triboson production was modelled using `SHERPA` 2.2.2. For top-quark pair production, `POWHEG-Box v2` was used. The production of single top quarks was simulated using `POWHEG-Box v1` [25–27]. The production of $t\bar{t}$ in association with vector bosons ($t\bar{t}V$) was modelled with `MADGRAPH5_aMC@NLO` 2.3.3 for $t\bar{t}W$, with `SHERPA` 2.2.1 and `MADGRAPH5_aMC@NLO` 2.3.3 for $t\bar{t}Z$, and with `MADGRAPH5_aMC@NLO` 2.2.2 for $t\bar{t}WW$. The $Z + \text{jets}$ processes were modelled using `SHERPA` 2.2.1.

The above theoretical calculations are accurate to a given order in perturbation theory for partonic final states. To correctly model the hadronic final state that interacts with the detector, parton showering, hadronisation and underlying-event algorithms were applied to the partonic final states predicted from each calculation. Those were modelled with `PYTHIA 8.186` [28] using the NNPDF2.3 [20] PDF and the A14 set of tuned parameters [29] for all the samples except for the ones from `SHERPA`, where those were simulated within the `SHERPA` program.

All samples were passed through a detailed simulation of the ATLAS detector [30] based on `GEANT4` [31], to produce predictions that can be directly compared with the data. Furthermore, simulated inelastic pp collisions were overlaid to model additional pp collisions in the same and neighbouring bunch crossings (pile-up). Simulated events were reweighted to match the pile-up conditions in the data. All simulated events were processed using the same reconstruction algorithms as used in data.

4 Event selection

The selection of the $\ell\ell\ell\ell jj$ and $\ell\ell\nu\nu jj$ events relies on multiple physics objects, including electrons, muons, and jets. The signal region (SR) is defined with a set of selection criteria, which were optimised to preferentially select the EW $Z Z jj$ events.

Events are first required to have a collision vertex associated with at least two tracks each with transverse momentum (p_T) > 0.5 GeV. The vertex with the highest sum of p_T^2 of the associated tracks is referred to as the primary vertex.

Muons are identified by tracks reconstructed in the MS and are matched to tracks reconstructed in the ID. In the region $2.5 < |\eta| < 2.7$, muons can also be identified by tracks from the MS alone, and these are called stand-alone muons. Identified muons are required to have $p_T > 7$ GeV. In the MS gap region ($|\eta| < 0.1$) muons are identified by an ID track with $p_T > 15$ GeV associated with a compatible calorimeter energy deposit, and are called calorimeter-tagged muons. Muons are required to have $|\eta| < 2.7$ (2.5) and satisfy the ‘loose’ (‘medium’) identification criterion [32] in the $\ell\ell\ell\ell jj$ ($\ell\ell\nu\nu jj$) channel. Electrons are reconstructed from energy deposits in the electromagnetic calorimeter matched to a track in the ID. Candidate electrons must satisfy the ‘loose’ (‘medium’) identification criterion [33] in the $\ell\ell\ell\ell jj$ ($\ell\ell\nu\nu jj$) channel, and have $p_T > 7$ GeV and $|\eta| < 2.47$. All electrons and muons must be isolated and satisfy the ‘FixedCutLoose’ and ‘loose’ isolation criteria [32, 33] in the $\ell\ell\ell\ell jj$ and $\ell\ell\nu\nu jj$ channels, respectively. Furthermore, electrons (muons) are required to have associated tracks satisfying $|d_0/\sigma_{d_0}| < 5$ (3) and $|z_0 \times \sin \theta| < 0.5$ mm, where d_0 is the transverse impact parameter relative to the beam line, σ_{d_0} is its uncertainty, and z_0 is the longitudinal impact parameter relative to the primary vertex.

Jets are reconstructed from clusters of calorimeter energy deposits using the anti- k_t algorithm [34, 35] with radius parameter $R = 0.4$. The jet energy scale is calibrated using simulation and further corrected with in situ methods [36]. A jet-vertex tagger [37] is applied to jets with $p_T < 60$ GeV and $|\eta| < 2.4$ to preferentially suppress jets that originated from pile-up. In addition, jets containing b -hadrons (b -jets) are identified using a multivariate b -tagging algorithm [38]. The chosen b -tagging algorithm has an efficiency of 85% for b -jets and a rejection factor of 33 against light-flavour jets.

An overlap-removal procedure detailed in Ref. [39] is applied to the selected leptons and jets in the $\ell\ell\nu\nu jj$ channel, to avoid ambiguities in the event selection and in the energy measurement of the physics objects. A similar approach is adopted in the $\ell\ell\ell\ell jj$ channel, except that leptons are given a higher priority to be kept when overlapping with jets, to enhance the selection efficiency.

The neutrinos in the $\ell\ell\nu\nu jj$ final state do not interact with the ATLAS detector and cannot be reconstructed. Their presence is identified using the missing transverse momentum vector (\vec{E}_T^{miss}), which is computed as the negative of the vector sum of transverse momenta of all the leptons and jets, as well as the tracks originating from the primary vertex but not associated with any of the leptons or jets [40]. The statistical significance of E_T^{miss} (E_T^{miss} -significance) is calculated using resolution information of physics objects used in the E_T^{miss} reconstruction [41].

In the $\ell\ell\ell\ell jj$ channel, quadruplets of leptons are formed by selecting two opposite-sign, same-flavour (OSSF) lepton pairs, where the leptons are required to be separated from each other by $\Delta R > 0.2$. At most one muon is allowed to be a stand-alone or calorimeter-tagged muon, and the three leading leptons must have $p_T > 20, 20$ and 10 GeV, respectively. All the $\ell^+\ell^-$ pairs are required to have an invariant mass ($m_{\ell^+\ell^-}$) greater than 10 GeV, to reject events from low-mass resonances. If multiple quadruplets are found, the one that minimises the sum of the differences between the dilepton masses and the nominal Z -boson

mass, $|m_{\ell^+\ell^-} - m_Z| + |m_{\ell'^+\ell'^-} - m_Z|$, is selected. The dilepton masses are required to be within the range 66–116 GeV.

In the $\ell\ellvvjj$ channel, candidate events are required to have one OSSF lepton pair with $m_{\ell^+\ell^-}$ in the range from 80 to 100 GeV, and the leading (sub-leading) lepton must have $p_T > 30$ (20) GeV. Events with b -tagged jets or additional leptons ($p_T > 7$ GeV and satisfying the ‘loose’ requirement) are rejected to reduce the background contributions from $t\bar{t}$ and WZ events. Events are required to have an E_T^{miss} -significance greater than 12 to suppress the background from $Z + \text{jets}$ processes.

In both channels, the two jets with the highest p_T and satisfying a negative product of jet rapidities ($y_{j_1} \times y_{j_2}$) are selected. In the $\ell\ell\ell\ell jj$ channel the jets are required to have $p_T > 30$ (40) GeV in the $|\eta| < 2.4$ ($2.4 < |\eta| < 4.5$) region, while in the $\ell\ellvvjj$ channel the leading (sub-leading) selected jet is required to have $p_T > 60$ (40) GeV. Finally, to further suppress background contributions, m_{jj} is required to be greater than 300 (400) GeV in the $\ell\ell\ell\ell jj$ ($\ell\ellvvjj$) channel, and $\Delta y(jj)$ is required to be greater than two. The harsher jet requirement in the $\ell\ellvvjj$ channel is optimised to suppress the more significant contamination from reducible backgrounds.

After selection, the resulting observed and expected yields are listed in Table 1, where in total 127 (82) data events are selected in the $\ell\ell\ell\ell jj$ ($\ell\ellvvjj$) channel. The expected event yields from each process are summed together and the interference effects between the EW and QCD processes are taken as an additional uncertainty in the EW $ZZjj$ predictions. Several control regions (CRs), defined with dedicated selections optimised to enhance the fractions of background events, are defined to constrain the contributions from the various background processes. The kinematic distributions from both channels, including the m_{jj} spectra in the $\ell\ell\ell\ell jj$ SR, QCD $ZZjj$ CR and $\ell\ellvvjj$ SR, as well as the invariant mass of the four-lepton system (m_{ZZ}) in the $\ell\ell\ell\ell jj$ SR, are presented in Figure 2. The background estimates, dedicated CRs and various sources of experimental and theoretical uncertainties are discussed in the following two sections.

The number of events in data is found to be consistent with the SM prediction including the EW $ZZjj$ contribution.

Table 1: Observed data and expected event yields in 139 fb^{-1} of data in the $\ell\ell\ell\ell jj$ and $\ell\ellvvjj$ signal regions. All the minor backgrounds are summed together as ‘Others’. Uncertainties in the predictions include both the statistical and systematic components.

Process	$\ell\ell\ell\ell jj$	$\ell\ellvvjj$
EW $ZZjj$	20.6 ± 2.5	12.3 ± 0.7
QCD $ZZjj$	77 ± 25	17.2 ± 3.5
QCD $ggZZjj$	13.1 ± 4.4	3.5 ± 1.1
Non-resonant- $\ell\ell$	–	21.4 ± 4.8
WZ	–	22.8 ± 1.1
Others	3.2 ± 2.1	1.2 ± 0.9
Total	114 ± 26	78.4 ± 6.2
Data	127	82

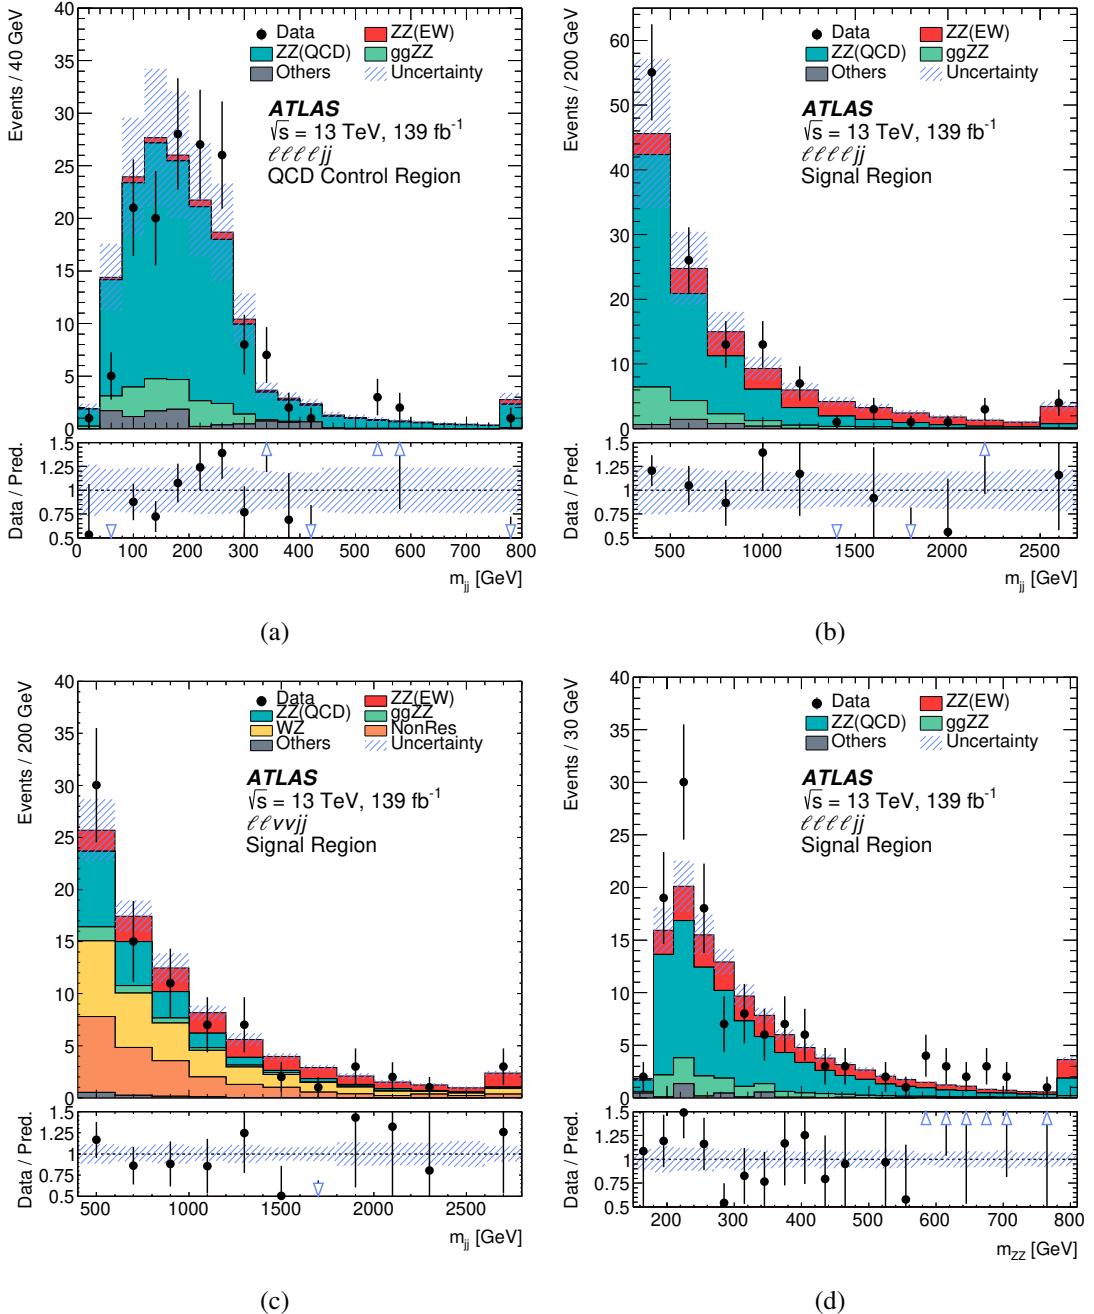

Figure 2: Observed and expected m_{jj} distributions in the (a) $\ell\ell\ell\ell jj$ QCD CR and the (b) $\ell\ell\ell\ell jj$ and (c) $\ell\ell\ell\ell jj$ signal regions, as well as the m_{ZZ} distribution in the (d) $\ell\ell\ell\ell jj$ signal region. The error bands include the expected experimental and theoretical uncertainties. The contributions from the QCD and EW production of $Z Z j j$ events are scaled by 0.96 and 1.35, respectively, which correspond to the observed normalisation factors in the statistical fit to the combined channel (Table 2). All the minor backgrounds are summed together as ‘Others’. The last bin includes the overflow events. The open arrows represent the out-of-range markers.

5 Background estimation

The backgrounds arise from two kinds of processes, one with final-state particles that are the same as those in the signal process, and the other one where one or more lepton candidates are misidentified in data.

In the $\ell\ell\ell\ell jj$ channel, the largest background arises from the QCD $ZZjj$ process, which has an identical final state to the EW $ZZjj$ process. The kinematic properties of the QCD $ZZjj$ background are estimated using the simulated events described in Section 3. However, the simulation is normalised to data in a dedicated EW-suppressed control region, defined by reversing either the m_{jj} or the $\Delta y(j,j)$ selection criteria. Furthermore, the modelling of the kinematic properties of the QCD $ZZjj$ simulation is validated in an additional EW-suppressed CR, which is defined by requiring the centrality to be larger than 0.5 for at least one of the selected Z bosons. The centrality is a variable that estimates the position of a Z-boson with respect to the rapidity span of the two outgoing hadronic jets [42]. Good agreement between data and simulation is found for most kinematic distributions. The impact on the signal extraction of a potential mismodelling of the m_{jj} distribution in the QCD $ZZjj$ simulation (seen in previous analyses [43–45]) is explicitly tested, by reweighting the QCD $ZZjj$ simulation in the SR using an m_{jj} -based correction factor that is defined as the ratio of data to simulation in the EW-suppressed CR at high centrality. The signal extracted using the reweighted and nominal QCD $ZZjj$ simulations are found to be in agreement when considering the statistical uncertainty on the m_{jj} -based correction itself.

Small background contributions from $Z + \text{jets}$, top-quark and $WZjj$ processes may contain misidentified leptons and are estimated using a method similar to that described in Ref. [46], where the lepton misidentification is measured in data regions with enhanced contributions from $Z + \text{jets}$ and top-quark processes. Minor background contributions from triboson and $t\bar{t}V$ production are estimated from simulation. All of those backgrounds collectively yield an estimated contribution of about 3% to the selected data sample in the $\ell\ell\ell\ell jj$ channel.

In the $\ell\ell vvjj$ channel, the normalisation and kinematic properties of QCD $ZZjj$ processes are modelled from simulation due to a large contamination from other processes, which are considered in dedicated CRs. The $WZjj$ background, with one lepton produced outside of the detector acceptance, is estimated using a data CR defined by requiring three selected leptons and a looser event selection, following the methodology explained in Ref. [47]. The simulation is found to overestimate the $WZjj$ contribution by 15% in this CR, and therefore the $WZjj$ yield in the SR is scaled by 0.85. The $WZjj$ distribution of the MD in the SR is evaluated from simulation, with the contributions from EW $WZjj$ processes scaled by 1.77, corresponding to the difference between data and simulation observed in a previous analysis, in a similar phase space [11], where the overall normalisation factor is found to be consistent with the one derived in this article. The $WWjj$ and $t\bar{t}$ processes are referred to as the non-resonant- $\ell\ell$ backgrounds, since they contain a lepton pair not originating from a Z or γ^* boson. The non-resonant- $\ell\ell$ background is estimated using a CR defined in data by applying the same selection as in the SR with the exception that an $e\mu$ pair is required, following the methodology explained in Ref. [47]. The MD distribution in the SR for the non-resonant- $\ell\ell$ process is estimated from simulation.

The $Z + \text{jets}$ background is largely suppressed, and the yield is evaluated by extrapolating the low E_T^{miss} -significance region distribution in data to the high E_T^{miss} -significance region using an exponential function, while the MD distribution in the SR is modelled by simulation. Small background contributions from triboson and $t\bar{t}V$ production are modelled with simulation. All of those backgrounds collectively yield an estimated contribution of about 1% to the selected data sample in the $\ell\ell vvjj$ channel.

6 Experimental and theoretical uncertainties

Systematic uncertainties associated with the prediction of each signal and background process are estimated. These uncertainties are either experimental or theoretical in nature, due to imperfect modelling of the detector in the simulation or the underlying physics of each process.

The major experimental uncertainties originate from the luminosity uncertainty, the energy measurements of leptons and jets, and the lepton reconstruction and selection efficiencies. Smaller experimental uncertainties are also considered, such as those due to the trigger selection efficiency, the calibration of the E_T^{miss} soft-term, the pile-up correction, and the b -jet identification efficiency. Overall, the total experimental uncertainty in the predicted yields is about 10% (5%) in the $\ell\ell\ell\ell jj$ ($\ell\ell\nu\nu jj$) channel, dominated by the jet and lepton calibration. The uncertainty in the combined 2015–2018 integrated luminosity is 1.7% [48], obtained using the LUCID-2 detector [49] for the primary luminosity measurements.

In addition, the uncertainties in the predicted yields from non- $ZZjj$ backgrounds are dominated by the statistical uncertainties from data in the dedicated CRs, which are about 15% for the overall backgrounds. The $WZjj$ shape uncertainty originates from experimental and theoretical uncertainties as well as from the uncertainty in the quoted EW $WZjj$ cross-section measurement. The non-resonant- $\ell\ell$ shape uncertainty is estimated by comparing the MD distributions from data and simulation. In addition, an uncertainty is assigned to the QCD $ZZjj$ processes by comparing the MD distributions in low and high pile-up conditions, to account for a potential mismodelling of pile-up in simulation. The differences in the predicted yields in different MD regions are below 10% except in the last bin in the QCD $ZZjj$ CR where it reaches 50% due to the statistical uncertainty of the simulated events.

The theoretical uncertainties of the EW and QCD $ZZjj$ processes include the uncertainties from PDFs, QCD scales, α_S , parton showering and hadronisation. The PDF uncertainty is estimated following the PDF4LHC [50] procedure. The effect of the QCD scale uncertainty is estimated by varying the renormalisation and factorisation scales following the procedure described in Ref. [51]. The parton showering and hadronisation uncertainty is estimated by comparing the nominal PYTHIA 8 parton showering with the alternative HERWIG 7 [52, 53] algorithm. The effect of the α_S uncertainty is estimated by varying the α_S value by ± 0.001 . The total theoretical uncertainty in the reconstructed event yields for the EW (QCD) $ZZjj$ process is estimated to be about 10% (30%). The interference effect between the EW and QCD processes is checked with MADGRAPH5_aMC@NLO 2.6.1, and found to make a relative contribution (to the EW signal) varying from 10% to 2% in the different MD regions, much smaller than the statistical uncertainty from data. This effect is taken as an uncertainty in the EW $ZZjj$ predictions. An additional uncertainty in the modelling of the QCD $ZZjj$ process is considered by comparing the predicted MD shapes from SHERPA to MADGRAPH5_aMC@NLO 2.6.1 at particle level in the case where two partons are explicitly required at LO in the ME calculation. The differences in the predicted yields in different MD regions range from -30% to $+20\%$.

7 Observation of electroweak $ZZjj$

To separate the EW $ZZjj$ processes from their backgrounds, MDs based on the Gradient Boosted Decision Tree algorithm [54] are trained with simulated events using the TMVA framework [55]. In each channel, a single MD is trained in the SR, which uses event kinematic information sensitive to the characteristics of the EW signal. The resulting MDs provide an optimal separation of the EW $ZZjj$ signal and the

backgrounds, where signal-like (background-like) events are featured in the high (low) MD region. In the $\ell\ell\ell\ell jj$ channel, twelve input variables are used: m_{jj} , $\Delta y(jj)$, p_T of the leading and sub-leading jets (p_T^{j1} and p_T^{j2}), $y_{j1} \times y_{j2}$, p_T of the Z boson reconstructed from the charged-lepton pair with the mass closer to the Z -boson mass, rapidity of both Z bosons (y_{Z1} and y_{Z2}), p_T and mass of the four-lepton system, p_T of the third lepton, p_T of the $ZZjj$ system divided by the scalar p_T sum of Z bosons and two jets (S_T). Thirteen input variables are utilised in the $\ell\ell\text{vv}jj$ channel: m_{jj} , $\Delta y(jj)$, $y_{j1} \times y_{j2}$, p_T^{j2} , E_T^{miss} , E_T^{miss} -significance, S_T , pseudorapidity and azimuthal angle differences between two charged leptons ($\Delta\eta$, $\Delta\phi$), ΔR , invariant mass of the charged-lepton pair, and p_T of leading and sub-leading leptons. The jet-related information provides the greatest sensitivity in the $\ell\ell\ell\ell jj$ channel, while both the jet-related and the dilepton-related variables are important in the $\ell\ell\text{vv}jj$ channel.

In the $\ell\ell\ell\ell jj$ channel the MD distributions in both the QCD $ZZjj$ CR (Figure 3(a)) and the SR (Figure 3(b)) are used in the statistical fit, while only the MD distribution in the SR (Figure 3(c)) is fitted in the $\ell\ell\text{vv}jj$ channel. The binning of MD distributions in the SRs is chosen to maximise the sensitivity of detecting EW $ZZjj$ events. In the $\ell\ell\ell\ell jj$ channel, the normalisation of QCD $ZZjj$ production ($\mu_{\text{QCD}}^{\ell\ell\ell\ell jj}$) is varied simultaneously in the fit in the SR and QCD CR. The ratio of measured fiducial cross-section to the SM prediction for EW $ZZjj$ production (μ_{EW}) is taken as the parameter of interest.

To examine the compatibility of the data and the signal-plus-background hypothesis, a test statistic is defined using the profile likelihood ratio method [56]. The statistical tests are performed in both the individual $\ell\ell\ell\ell jj$ and $\ell\ell\text{vv}jj$ channels, and in the combined channel. The experimental systematic uncertainties are considered as correlated in all the bins and regions whenever applicable. The theoretical uncertainties for $ZZjj$ production are treated as uncorrelated between the $\ell\ell\ell\ell jj$ and $\ell\ell\text{vv}jj$ channels, due to the different fiducial volume definitions. The QCD scale uncertainty for QCD $ZZjj$ production can be assessed in various ways in terms of correlations between different fitted regions and is conservatively treated as uncorrelated between the SR and the QCD CR in the $\ell\ell\ell\ell jj$ channel. Furthermore, the generator modelling uncertainty for QCD $ZZjj$ production is treated as uncorrelated between the low and high MD regions.

The results are shown in Table 2. From the combined channel, the observed μ_{EW} is 1.35 ± 0.34 , while $\mu_{\text{QCD}}^{\ell\ell\ell\ell jj}$ is determined to be 0.96 ± 0.22 . The statistical component accounts for 88% of the total uncertainty in μ_{EW} . The probability that the background can randomly fluctuate to produce a measured likelihood ratio at least as signal-like as the excess observed in the data is 1.9×10^{-8} , leading to the observation of EW $ZZjj$ production. Correspondingly, with a normalised Gaussian distribution, the background-only hypothesis is rejected at 5.5σ (4.3σ) from the data (expectation). The EW $ZZjj$ cross-section in the combined fiducial volume, formed by combining the respective fiducial regions in the $\ell\ell\ell\ell jj$ and $\ell\ell\text{vv}jj$ channels, is found to be 0.82 ± 0.21 fb, calculated as μ_{EW} multiplied by the SM prediction of 0.61 ± 0.03 fb.

Table 2: Observed μ_{EW} and $\mu_{\text{QCD}}^{\ell\ell\ell\ell jj}$, as well as the observed and expected significance of EW $ZZjj$ processes from the individual $\ell\ell\ell\ell jj$ and $\ell\ell\text{vv}jj$ channels, and the combined fits. The full set of statistical and systematic uncertainties is included.

	μ_{EW}	$\mu_{\text{QCD}}^{\ell\ell\ell\ell jj}$	Significance Obs. (Exp.)
$\ell\ell\ell\ell jj$	1.5 ± 0.4	0.95 ± 0.22	$5.5 (3.9)\sigma$
$\ell\ell\text{vv}jj$	0.7 ± 0.7	—	$1.2 (1.8)\sigma$
Combined	1.35 ± 0.34	0.96 ± 0.22	$5.5 (4.3)\sigma$

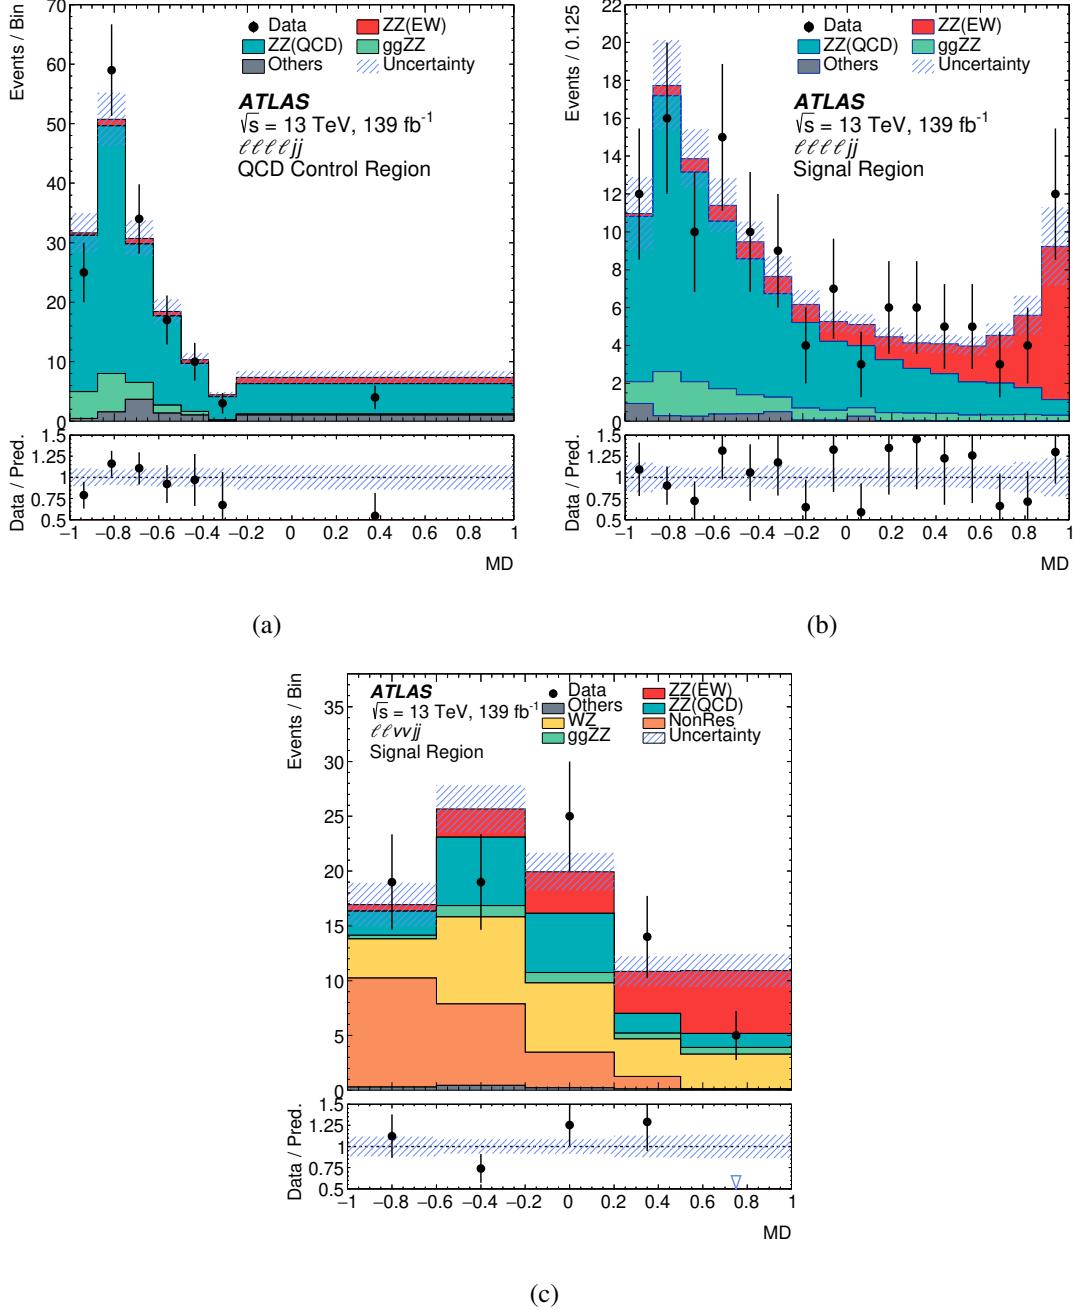

Figure 3: Observed and expected multivariate discriminant distributions after the statistical fit in the (a) $\ell\ell\ell\ell jj$ QCD CR, and in the (b) $\ell\ell\ell\ell jj$ and (c) $\ell\ell vv jj$ signal regions. The error bands include the experimental and theoretical uncertainties, as well as the uncertainties in μ_{EW} and $\mu_{\text{QCD}}^{\ell\ell\ell\ell jj}$. All the minor backgrounds are summed together as ‘Others’. The statistical uncertainties of the data are shown as error bars. The open arrows represent the out-of-range markers.

8 Measurement of fiducial cross-sections

In addition to the observation of the EW $ZZjj$ process, the cross-sections for the production of inclusive $ZZjj$ are also measured in the $\ell\ell\ell\ell jj$ and $\ell\ell\nu\nu jj$ channels. This measurement, corrected for detector inefficiency and resolution without any further theoretical interpretation, provides the most model-independent results. The cross-sections are measured following the formula $\sigma = (N_{\text{data}} - N_{\text{bkg}})/(L \times C)$, where N_{data} and N_{bkg} refer to the number of events in data and the expected number of background events from non- $ZZjj$ processes respectively, L refers to the integrated luminosity, and C is the correction factor to extrapolate the QCD and EW $ZZjj$ events from detector level to the fiducial volume, calculated as the ratio of the number of $ZZjj$ events passing the detector-level event selection to the number of events selected in the fiducial volume.

The definitions of the fiducial volumes closely follow the detector-level selections, using ‘particle-level’ electrons, muons, E_T^{miss} and jets, which are reconstructed in simulation from stable final-state particles, prior to their interactions with the detector, following the procedure described in Ref. [51]. In the $\ell\ell\ell\ell jj$ channel, the dilepton mass requirement is relaxed (relative to the detector-level selection) to the wider range 60–120 GeV to ensure compatibility with the previous CMS publication [13]. In the $\ell\ell\nu\nu jj$ channel, both the electrons and muons are selected in the $|\eta| < 2.5$ region to simplify the charged-lepton selections. In addition, no requirement is placed on the E_T^{miss} -significance due to the complexity of defining this variable at particle level; however, the particle-level E_T^{miss} is required to be greater than 130 GeV. All the other kinematic selection requirements have the same definition as the detector-level ones.

The C -factors are found to be $(69.9 \pm 3.1)\%$ in the $\ell\ell\ell\ell jj$ channel, and $(21.6 \pm 1.2)\%$ in the $\ell\ell\nu\nu jj$ channel, where the errors reflect the total uncertainties. The smaller C -factor in the $\ell\ell\nu\nu jj$ channel is due to the large event migration effect in events passing the E_T^{miss} selection requirement at particle level that have a small E_T^{miss} -significance at detector level. The measured and predicted fiducial cross-sections are presented in Table 3. Uncertainties from different sources are presented explicitly. The data statistical uncertainty dominates, while the experimental uncertainties related to jet measurements and the background estimates are the major systematic uncertainties in the $\ell\ell\ell\ell jj$ and $\ell\ell\nu\nu jj$ channels, respectively. The measurements of 1.27 ± 0.14 fb for the $\ell\ell\ell\ell jj$ channel and 1.22 ± 0.35 fb for the $\ell\ell\nu\nu jj$ channel are compatible with the SM predictions. The measurement precision in the $\ell\ell\ell\ell jj$ channel is better than the accuracy of the theoretical prediction.

Table 3: Measured and predicted fiducial cross-sections in both the $\ell\ell\ell\ell jj$ and $\ell\ell\nu\nu jj$ channels for the inclusive $ZZjj$ processes. Uncertainties due to different sources are presented explicitly, including the one from the statistical uncertainty of the data and simulated samples (stat), the one from the theoretical predictions (theo), the experimental ones due to the lepton and jet calibrations (exp), the ones from background estimates (bkg), and the one from the luminosity (lumi).

	Measured fiducial σ [fb]	Predicted fiducial σ [fb]
$\ell\ell\ell\ell jj$	$1.27 \pm 0.12(\text{stat}) \pm 0.02(\text{theo}) \pm 0.07(\text{exp}) \pm 0.01(\text{bkg}) \pm 0.03(\text{lumi})$	$1.14 \pm 0.04(\text{stat}) \pm 0.20(\text{theo})$
$\ell\ell\nu\nu jj$	$1.22 \pm 0.30(\text{stat}) \pm 0.04(\text{theo}) \pm 0.06(\text{exp}) \pm 0.16(\text{bkg}) \pm 0.03(\text{lumi})$	$1.07 \pm 0.01(\text{stat}) \pm 0.12(\text{theo})$

9 Conclusion

The rare electroweak production of $ZZjj$ events is observed using 139 fb^{-1} of $\sqrt{s} = 13\text{ TeV}$ proton–proton collision data collected with the ATLAS detector. The events are identified within a large hadron-collision background, owing to an optimised analysis strategy as well as the excellent performance of the LHC and the ATLAS detector. The measurement of the cross-section for electroweak boson scattering producing a pair of Z bosons is consistent with Standard Model predictions. This result is a milestone in studies of electroweak $VVjj$ production at the LHC, and an important contribution to understanding the nature of electroweak symmetry breaking in the Standard Model.

Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWFW and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF and DNSRC, Denmark; IN2P3-CNRS and CEA-DRF/IRFU, France; SRNSFG, Georgia; BMBF, HGF and MPG, Germany; GSRT, Greece; RGC and Hong Kong SAR, China; ISF and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; NWO, Netherlands; RCN, Norway; MNiSW and NCN, Poland; FCT, Portugal; MNE/IFA, Romania; MES of Russia and NRC KI, Russia Federation; JINR; MESTD, Serbia; MSSR, Slovakia; ARRS and MIZŠ, Slovenia; DST/NRF, South Africa; MINECO, Spain; SRC and Wallenberg Foundation, Sweden; SERI, SNSF and Cantons of Bern and Geneva, Switzerland; MOST, Taiwan; TAEK, Turkey; STFC, United Kingdom; DOE and NSF, United States of America. In addition, individual groups and members have received support from BCKDF, CANARIE, Compute Canada and CRC, Canada; ERC, ERDF, Horizon 2020, Marie Skłodowska-Curie Actions and COST, European Union; Investissements d’Avenir Labex, Investissements d’Avenir Idex and ANR, France; DFG and AvH Foundation, Germany; Herakleitos, Thales and Aristeia programmes co-financed by EU-ESF and the Greek NSRF, Greece; BSF-NSF and GIF, Israel; CERCA Programme Generalitat de Catalunya and PROMETEO Programme Generalitat Valenciana, Spain; Göran Gustafssons Stiftelse, Sweden; The Royal Society and Leverhulme Trust, United Kingdom.

The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN, the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA), the Tier-2 facilities worldwide and large non-WLCG resource providers. Major contributors of computing resources are listed in Ref. [57].
