ABSTRACT

We have computed the four lowest even- N moments of all four splitting functions for the evolution of flavour-singlet parton densities of hadrons at the fourth order in the strong coupling constant α_s . The perturbative expansion of these moments, and hence of the splitting functions for momentum fractions $x \gtrsim 0.1$, is found to be well behaved with relative α_s -coefficients of order one and sub-percent effects on the scale derivatives of the quark and gluon distributions at $\alpha_s \lesssim 0.2$. More intricate computations, including other approaches such as the operator-product expansion, are required to cover the full x -range relevant to LHC analyses. Our results are presented analytically for a general gauge group for detailed checks and validations of such future calculations.

Fully consistent analyses of hard processes with initial-state hadrons at the (next-to) n -leading order (N^n LO) of renormalization-group improved perturbative QCD require parton distributions functions (PDFs) evolved with the $(n+1)$ -loop splitting functions. Over the past years, N^2 LO (= NNLO) has become the standard approximation for many processes. Following pioneering computations of their lowest integer- N Mellin moments in refs. [1,2], the corresponding 3-loop splitting functions were obtained in refs. [3,4].

For certain benchmark cases, in particular Higgs-boson production at the LHC [5], N^2 LO calculations are not sufficiently accurate, hence the 4-loop splitting functions need to be calculated. These have been determined for the flavour non-singlet quark-quark case in ref. [6] – analytically in the limit of a large number of colours n_c , and numerically for the remaining contributions – and for the (next-to-) leading contributions for a large number of flavours n_f in ref. [7].

Here we present, as a first significant step towards at least approximate expressions for the 4-loop singlet splitting functions for use in phenomenological analyses, their lowest four even moments $N = 2, \dots, 8$ in the standard $\overline{\text{MS}}$ scheme, thus extending the computations of ref. [2] by one order in the strong coupling α_s . Following the approach of refs. [2,4] our calculations are performed via physical quantities in deep-inelastic scattering, i.e., instead of working with 4-loop off-shell flavour-singlet operator matrix elements (OMEs) which, at this point, is still theoretically challenging. Our present results, obtained analytically for a general gauge group, should also be useful for checking and validating future OME computations of these quantities.

The evolution equations for the flavour-singlet quark and gluon PDFs of hadrons,

$$q_s(x, \mu_f^2) = \sum_{i=1}^{n_f} \left[q_i(x, \mu_f^2) + \bar{q}_i(x, \mu_f^2) \right] \quad \text{and} \quad g(x, \mu_f^2), \quad (1)$$

are

$$\frac{d}{d \ln \mu_f^2} \begin{pmatrix} q_s \\ g \end{pmatrix} = \begin{pmatrix} P_{qq} & P_{qg} \\ P_{gq} & P_{gg} \end{pmatrix} \otimes \begin{pmatrix} q_s \\ g \end{pmatrix}. \quad (2)$$

Here \otimes represents the Mellin convolution in the momentum variable, and μ_f is the factorization scale. For the determination of the splitting functions P_{ik} , the renormalization scale can be identified with μ_f without loss of information. The even- N moments of splitting functions in eq. (2) are identical to the anomalous dimensions of twist-2 spin- N operators up to a conventional sign,

$$\gamma_{ik}(N, \alpha_s) = - \int_0^1 dx x^{N-1} P_{ik}(x, \alpha_s) . \quad (3)$$

Their perturbative expansions can be written as

$$\gamma_{ik}(N, \alpha_s) = \sum_{n=0} a_s^{n+1} \gamma_{ik}^{(n)}(x) \quad \text{with} \quad a_s \equiv \frac{\alpha_s(\mu_f^2)}{4\pi} . \quad (4)$$

The quark-quark entry in eq. (3) can be expressed as $\gamma_{qq} = \gamma_{ns}^+ + \gamma_{ps}$ in terms of the non-singlet anomalous dimension γ_{ns}^+ for quark-antiquark sums addressed at four loops in ref. [6] and a pure-singlet contribution γ_{ps} which is suppressed at $N \gg 1$. At asymptotically large N the diagonal $\overline{\text{MS}}$ entries $\gamma_{kk}(N)$ in eq. (2) are governed by the (lightlike) cusp anomalous dimensions A_k [8], viz $\gamma_{kk}(N) = A_k \ln N + \mathcal{O}(1)$, which are now fully known at four loops [9,10].

The 4-loop contributions to the pure-singlet anomalous dimensions in eq. (4) at $N = 2, 4, 6$ are

$$\begin{aligned} \gamma_{ps}^{(3)}(N=2) &= n_f C_F^3 \left(\frac{227938}{2187} + \frac{1952}{81} \zeta_3 + \frac{256}{9} \zeta_4 - \frac{640}{3} \zeta_5 \right) \\ &+ n_f C_A C_F^2 \left(-\frac{162658}{6561} + \frac{8048}{27} \zeta_3 - \frac{1664}{9} \zeta_4 + \frac{320}{9} \zeta_5 \right) \\ &+ n_f C_A^2 C_F \left(-\frac{410299}{6561} - \frac{26896}{81} \zeta_3 + \frac{1408}{9} \zeta_4 + \frac{4480}{27} \zeta_5 \right) \\ &+ n_f \frac{d_R^{abcd} d_R^{abcd}}{n_c} \left(\frac{1024}{9} + \frac{256}{9} \zeta_3 - \frac{2560}{9} \zeta_5 \right) - n_f^2 C_F^2 \left(\frac{73772}{6561} + \frac{5248}{81} \zeta_3 - \frac{320}{9} \zeta_4 \right) \\ &+ n_f^2 C_A C_F \left(\frac{160648}{6561} + 48 \zeta_3 - \frac{320}{9} \zeta_4 \right) + n_f^3 C_F \left(-\frac{1712}{729} + \frac{128}{27} \zeta_3 \right), \end{aligned} \quad (5)$$

For brevity, we here write down the results at $N=8$ only numerically for the case of QCD:

$$\gamma_{ps}^{(3)}(N=8) = -24.014550 n_f + 3.2351935 n_f^2 - 0.0078892 n_f^3, \quad (17)$$

$$\gamma_{qg}^{(3)}(N=8) = 294.58768 n_f - 135.37676 n_f^2 - 3.6097756 n_f^3, \quad (18)$$

$$\gamma_{gq}^{(3)}(N=8) = -2803.6441 + 436.393057 n_f + 1.8149462 n_f^2 + 0.0735886 n_f^3, \quad (19)$$

$$\gamma_{gg}^{(3)}(N=8) = 62279.744 - 17150.6967 n_f + 785.88061 n_f^2 + 1.8933103 n_f^3. \quad (20)$$

In eqs. (5) – (16) C_F and C_A are the standard colour factors with $C_F = 4/3$ and $C_A = n_c = 3$ in QCD. The terms with the quartic group invariants $d_A^{abcd} d_A^{abcd}$, $d_R^{abcd} d_A^{abcd}$ and $d_R^{abcd} d_R^{abcd}$ agree with the results of ref. [11] where these particular contributions were obtained to much higher values of N using OME calculations. All coefficients of the Riemann- ζ value $\zeta_4 = \pi^4/90$ agree with the all- N predictions in eqs. (9) – (12) of ref. [12] based on the ‘no- π^2 ’ conjecture of ref. [13]. The n_f^3 contributions to all four anomalous dimension are known for all N [7], see also refs. [14].

The above results lead to the numerical expansions

$$\begin{aligned} \gamma_{qq}(2, 3) &= 0.282942 \alpha_s \left(1 + 0.736828 \alpha_s + 0.517255 \alpha_s^2 + 0.756972 \alpha_s^3 + \dots \right), \\ \gamma_{qq}(2, 4) &= 0.282942 \alpha_s \left(1 + 0.621883 \alpha_s + 0.146133 \alpha_s^2 + 0.362201 \alpha_s^3 + \dots \right), \end{aligned} \quad (21)$$

$$\begin{aligned} \gamma_{qq}(4, 3) &= 0.555274 \alpha_s \left(1 + 0.756202 \alpha_s + 0.672283 \alpha_s^2 + 0.701628 \alpha_s^3 + \dots \right), \\ \gamma_{qq}(4, 4) &= 0.555274 \alpha_s \left(1 + 0.680253 \alpha_s + 0.427783 \alpha_s^2 + 0.345861 \alpha_s^3 + \dots \right), \end{aligned} \quad (22)$$

$$\begin{aligned} \gamma_{qq}(6, 3) &= 0.716450 \alpha_s \left(1 + 0.725387 \alpha_s + 0.685289 \alpha_s^2 + 0.663440 \alpha_s^3 + \dots \right), \\ \gamma_{qq}(6, 4) &= 0.716450 \alpha_s \left(1 + 0.648931 \alpha_s + 0.426442 \alpha_s^2 + 0.324781 \alpha_s^3 + \dots \right), \end{aligned} \quad (23)$$

$$\begin{aligned} \gamma_{qq}(8, 3) &= 0.832237 \alpha_s \left(1 + 0.710075 \alpha_s + 0.650750 \alpha_s^2 + 0.643336 \alpha_s^3 + \dots \right), \\ \gamma_{qq}(8, 4) &= 0.832237 \alpha_s \left(1 + 0.632824 \alpha_s + 0.423498 \alpha_s^2 + 0.312139 \alpha_s^3 + \dots \right) \end{aligned} \quad (24)$$

and

$$\begin{aligned} \gamma_{qg}(2, 3) &= -0.159155 \alpha_s \left(1 + 0.900404 \alpha_s + 0.012215 \alpha_s^2 - 0.055970 \alpha_s^3 + \dots \right), \\ \gamma_{qg}(2, 4) &= -0.212207 \alpha_s \left(1 + 0.900404 \alpha_s - 0.102840 \alpha_s^2 - 0.236731 \alpha_s^3 + \dots \right), \end{aligned} \quad (25)$$

$$\begin{aligned} \gamma_{qg}(4, 3) &= -0.087535 \alpha_s \left(1 - 0.280121 \alpha_s - 0.893969 \alpha_s^2 - 0.022754 \alpha_s^3 + \dots \right), \\ \gamma_{qg}(4, 4) &= -0.116714 \alpha_s \left(1 - 0.280121 \alpha_s - 0.998634 \alpha_s^2 + 0.129659 \alpha_s^3 + \dots \right), \end{aligned} \quad (26)$$

$$\begin{aligned} \gamma_{qg}(6, 3) &= -0.062525 \alpha_s \left(1 - 0.838938 \alpha_s - 1.064575 \alpha_s^2 + 0.145572 \alpha_s^3 + \dots \right), \\ \gamma_{qg}(6, 4) &= -0.083367 \alpha_s \left(1 - 0.838938 \alpha_s - 1.150113 \alpha_s^2 + 0.441744 \alpha_s^3 + \dots \right), \end{aligned} \quad (27)$$

$$\begin{aligned} \gamma_{qg}(8, 3) &= -0.049728 \alpha_s \left(1 - 1.255845 \alpha_s - 1.091729 \alpha_s^2 + 0.353099 \alpha_s^3 + \dots \right), \\ \gamma_{qg}(8, 4) &= -0.065430 \alpha_s \left(1 - 1.255845 \alpha_s - 1.160288 \alpha_s^2 + 0.746929 \alpha_s^3 + \dots \right) \end{aligned} \quad (28)$$

for the upper row of the anomalous-dimension matrix, where the arguments of γ_{ik} are N and n_f ; the values for $n_f = 5$ have been suppressed for brevity. The independent lower-row expansions – the values at $N = 2$ are fixed by the momentum sum-rule relations (11) and (14) – are given by

$$\begin{aligned} \gamma_{gq}(4, 3) &= -0.077809 \alpha_s \left(1 + 1.165483 \alpha_s + 1.163066 \alpha_s^2 + 1.474368 \alpha_s^3 + \dots \right), \\ \gamma_{gq}(4, 4) &= -0.077809 \alpha_s \left(1 + 1.115164 \alpha_s + 0.823447 \alpha_s^2 + 0.883269 \alpha_s^3 + \dots \right), \end{aligned} \quad (29)$$

$$\begin{aligned} \gamma_{gq}(6, 3) &= -0.044462 \alpha_s \left(1 + 1.314556 \alpha_s + 1.360970 \alpha_s^2 + 1.726679 \alpha_s^3 + \dots \right), \\ \gamma_{gq}(6, 4) &= -0.044462 \alpha_s \left(1 + 1.301901 \alpha_s + 1.051619 \alpha_s^2 + 1.126955 \alpha_s^3 + \dots \right), \end{aligned} \quad (30)$$

$$\begin{aligned} \gamma_{gq}(8, 3) &= -0.031157 \alpha_s \left(1 + 1.416509 \alpha_s + 1.468523 \alpha_s^2 + 1.899893 \alpha_s^3 + \dots \right), \\ \gamma_{gq}(8, 4) &= -0.031157 \alpha_s \left(1 + 1.430863 \alpha_s + 1.183046 \alpha_s^2 + 1.318370 \alpha_s^3 + \dots \right) \end{aligned} \quad (31)$$

and

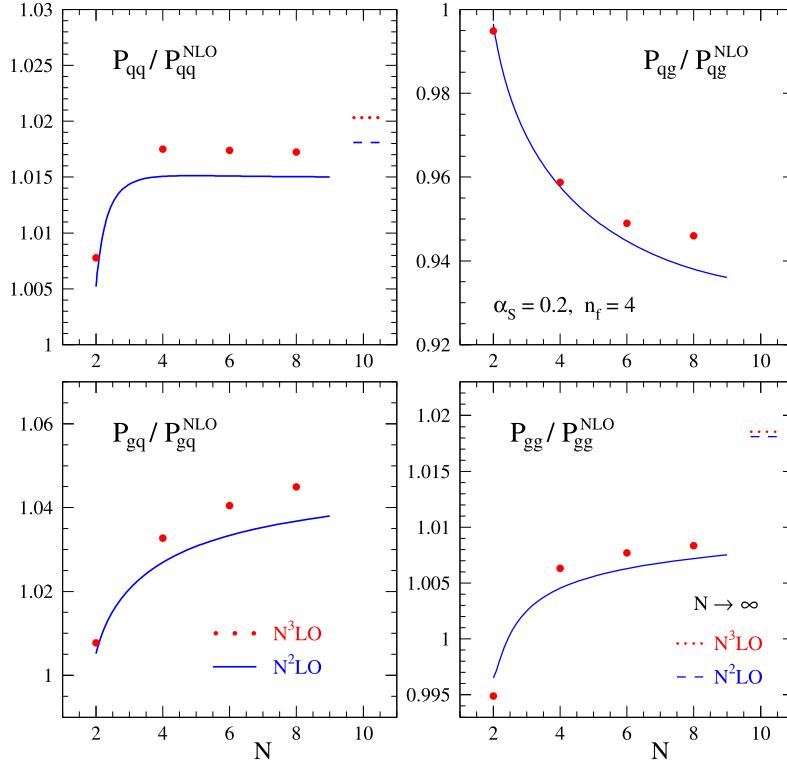

Fig. 1. Moments of the splitting functions (2) at NNLO (lines) and N^3 LO (even- N points) at $\alpha_s = 0.2$ and $n_f = 4$, normalized to the NLO results. Also shown are the qq and gg large- N limits.

$$\begin{aligned}\gamma_{gg}(4, 3) &= 1.161831 \alpha_s \left(1 + 0.475446 \alpha_s + 0.333272 \alpha_s^2 + 0.478025 \alpha_s^3 + \dots \right), \\ \gamma_{gg}(4, 4) &= 1.214882 \alpha_s \left(1 + 0.383536 \alpha_s + 0.121966 \alpha_s^2 + 0.240469 \alpha_s^3 + \dots \right),\end{aligned}\quad (32)$$

$$\begin{aligned}\gamma_{gg}(6, 3) &= 1.574497 \alpha_s \left(1 + 0.489287 \alpha_s + 0.380902 \alpha_s^2 + 0.429696 \alpha_s^3 + \dots \right), \\ \gamma_{gg}(6, 4) &= 1.627549 \alpha_s \left(1 + 0.393705 \alpha_s + 0.169676 \alpha_s^2 + 0.190156 \alpha_s^3 + \dots \right),\end{aligned}\quad (33)$$

$$\begin{aligned}\gamma_{gg}(8, 3) &= 1.851503 \alpha_s \left(1 + 0.497734 \alpha_s + 0.404644 \alpha_s^2 + 0.398779 \alpha_s^3 + \dots \right), \\ \gamma_{gg}(8, 4) &= 1.904554 \alpha_s \left(1 + 0.401746 \alpha_s + 0.194306 \alpha_s^2 + 0.157133 \alpha_s^3 + \dots \right).\end{aligned}\quad (34)$$

Except for γ_{qg} and γ_{gg} at $N = 8$ these numerical expansions have been presented before in ref. [15].

The results for the qq and gg cases at asymptotically (and unphysically) large values of N read

$$\begin{aligned}\gamma_{qq}(N, 3) &= a_s \gamma_{qq}^{(0)}(N, 3) \left(1 + 0.726574 \alpha_s + 0.734054 \alpha_s^2 + 0.664730 \alpha_s^3 + \dots \right), \\ \gamma_{qq}(N, 4) &= a_s \gamma_{qq}^{(0)}(N, 4) \left(1 + 0.638154 \alpha_s + 0.509978 \alpha_s^2 + 0.316848 \alpha_s^3 + \dots \right)\end{aligned}\quad (35)$$

and

$$\begin{aligned}\gamma_{gg}(N, 3) &= a_s \gamma_{gg}^{(0)}(N, 3) \left(1 + 0.726574 \alpha_s + 0.734054 \alpha_s^2 + 0.415609 \alpha_s^3 + \dots \right), \\ \gamma_{gg}(N, 4) &= a_s \gamma_{gg}^{(0)}(N, 4) \left(1 + 0.638154 \alpha_s + 0.509978 \alpha_s^2 + 0.064476 \alpha_s^3 + \dots \right)\end{aligned}\quad (36)$$

due to their relation to the cusp anomalous dimensions A_k . The quark and gluon results are identical up to the ‘Casimir scaling’ of the prefactors, $\gamma_{qq}^{(0)}(N, n_f) = 4 C_F \ln N$ and $\gamma_{gg}^{(0)}(N, n_f) = 4 C_A \ln N$, to three loops and are related by a generalized (not numerical, except in the large- n_c limit, due to the presence of the quartic group invariants) Casimir scaling [11,16] at four loops.

The relative size of the N^2 LO and N^3 LO contributions in eqs. (21) – (36) is illustrated in Fig. 1 for $n_f = 4$ at $\alpha_s = 0.2$: The N^3 LO corrections amount to less than 1%, and less than 0.5% of the NLO results except for P_{qg} , at $N = 8$ and P_{gg} , the quantity with the lowest leading-order values, at $N \geq 4$. Unlike in the quark case, see also ref. [17] where also a first estimate of the five-loop contribution to A_q has been obtained, the N^2 LO and N^3 LO large- N limits in the gluon case do not, in general, roughly agree with values in the range $4 \leq N \leq 8$ normalized as in eqs. (21) – (34).

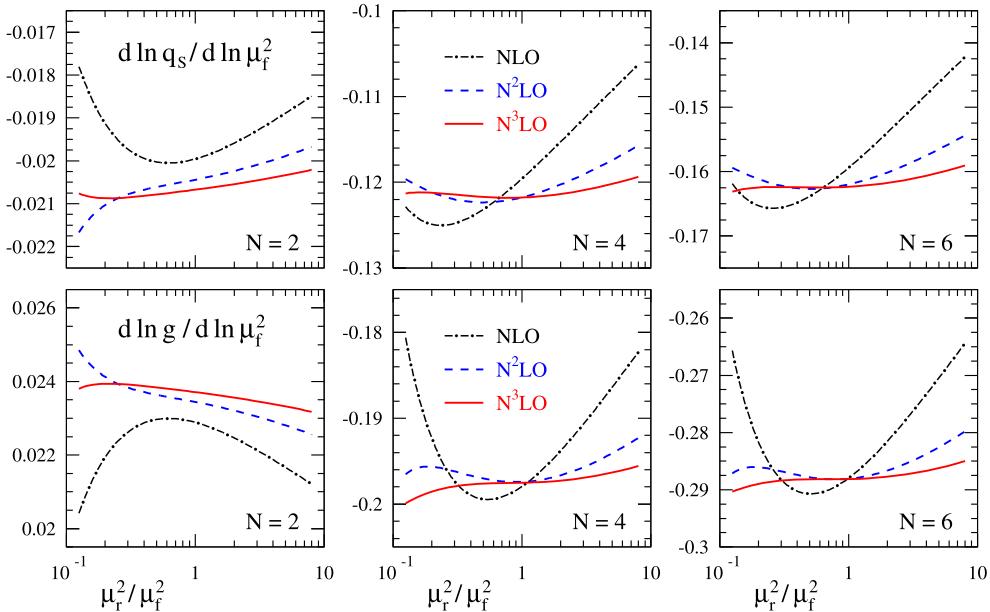

Fig. 2. The dependence of the logarithmic factorization-scale derivatives of the singlet PDFs on the renormalization scale μ_r at $N = 2$ (where the very small scaling violations of q_s and g are related by the momentum sum rule), $N = 4$ and $N = 6$ for the initial distributions (37).

The resulting low- N expansion for the evolution (2) of the singlet quark and gluon PDFs is illustrated in Fig. 2 for the schematic but sufficiently realistic order-independent model input [4]

$$\begin{aligned} xq_s(x, \mu_0^2) &= 0.6x^{-0.3}(1-x)^{3.5} \left(1 + 5.0x^{0.8}\right), \\ xg(x, \mu_0^2) &= 1.6x^{-0.3}(1-x)^{4.5} \left(1 - 0.6x^{0.3}\right) \end{aligned} \quad (37)$$

with $\alpha_s(\mu_0^2) = 0.2$ and $n_f = 4$. The $N^3\text{LO}$ corrections are very small at the standard choice $\mu_r = \mu_f \equiv \mu_0$ of the renormalization scale. They lead to a reduction of the scale dependence to about 1% (full width) at $N \geq 4$ for the conventional range $\frac{1}{4}\mu_f^2 \leq \mu_r^2 \leq 4\mu_f^2$.

To summarize, we have employed the theoretical framework of refs. [1–4] together with an optimized in-house version of the FORM [18] program FORCER for 4-loop propagator integrals [19] to compute the moments $N = 2, 4, 6$, and 8 of all $N^3\text{LO}$ flavour-singlet splitting functions. The numerical effect of these contributions is small, but more work is needed to arrive at sufficient ‘data’ for a $N^3\text{LO}$ analogue of the earlier approximate $N^2\text{LO}$ splitting functions of ref. [20].

Acknowledgements

This work has been supported by the European Research Council (ERC) via the grants 320651 (*HEPGAME*) and 694712 (*PertQCD*), by the European Cooperation in Science and Technology (COST) via COST Action CA16201 *PARTICLEFACE*, by the Deutsche Forschungsgemeinschaft (DFG) through the Research Unit FOR 2926, *Next Generation pQCD for Hadron Structure: Preparing for the EIC*, project number 40824754 and DFG grant MO 1801/4-1, by the Swiss National Science Foundation (SNSF) grant 179016, by the JSPS KAKENHI grants 19K03831 and 21K03583, and by the UK Science & Technology Facilities Council (STFC) grants ST/L000431/1 and ST/T000988/1. Some of our computations were carried out on the Dutch national e-infrastructure with the support of the SURF Cooperative and the PDP Group at Nikhef, and on the ulgqcd computer cluster in Liverpool which was funded by the STFC grant ST/H008837/1.

Appendix A. Supplementary material
