## ABSTRACT

Many extensions of the Standard Model predict the production of dark matter particles at the LHC. Sufficiently light dark matter particles may be produced in decays of the Higgs boson that would appear invisible to the detector. This Letter presents a statistical combination of searches for  $H \rightarrow$  invisible decays where multiple production modes of the Standard Model Higgs boson are considered. These searches are performed with the ATLAS detector using  $139 \text{ fb}^{-1}$  of proton-proton collisions at a centre-of-mass energy of  $\sqrt{s} = 13 \text{ TeV}$  at the LHC. In combination with the results at  $\sqrt{s} = 7 \text{ TeV}$  and  $8 \text{ TeV}$ , an upper limit on the  $H \rightarrow$  invisible branching ratio of 0.107 (0.077) at the 95% confidence level is observed (expected). These results are also interpreted in the context of models where the 125 GeV Higgs boson acts as a portal to dark matter, and limits are set on the scattering cross-section of weakly interacting massive particles and nucleons.

## 1. Introduction

\* E-mail address: [atlas.publications@cern.ch](mailto:atlas.publications@cern.ch).

Compelling astrophysical evidence suggests that dark matter (DM) comprises most of the matter in the universe [1–4]. However,

its nature is still unknown and poses one of the central questions in modern physics. A possible candidate for DM is a massive, stable and electrically neutral particle  $\chi$ , interacting weakly with the known particles of the Standard Model (SM).

Several theoretical frameworks predict the production of DM particles in proton–proton collisions at the Large Hadron Collider (LHC) [5–7]. In a wide class of those models, the 125 GeV Higgs boson [8,9] acts as a portal between a dark sector and the SM sector, either through Yukawa-type couplings to fermionic DM, or other mechanisms [10–23]. If kinematically allowed, pairs of DM particles can then be produced via the decay of the Higgs boson. The DM particles would traverse the detector without interacting and are inferred indirectly through the presence of missing transverse momentum ( $E_T^{\text{miss}}$ )<sup>1</sup> in the interaction. This decay channel is therefore called “invisible.” In the SM, the branching fraction to invisible final states is about 0.1% [24] arising from the decay of the Higgs boson via  $ZZ^* \rightarrow 4\nu$ .

Direct searches for invisible decays of the Higgs boson were carried out with the ATLAS detector [25,26] during Run 1 of the LHC, using up to  $4.7 \text{ fb}^{-1}$  of  $pp$  collision data at a centre-of-mass energy of  $\sqrt{s} = 7 \text{ TeV}$  and up to  $20.3 \text{ fb}^{-1}$  at  $8 \text{ TeV}$ . Various event topologies were considered: vector boson fusion (VBF) [27], production in association with a  $Z$  boson ( $ZH$ ) that decays into a pair of electrons or muons [28], and with a  $W$  or  $Z$  boson that decays into hadrons [29]. A statistical combination of these ATLAS searches resulted in an observed (expected) upper limit at the 95% confidence level (CL) on the invisible Higgs boson branching ratio of  $\mathcal{B}_{H \rightarrow \text{inv}} < 0.25 (0.27^{+0.10}_{-0.08})$  [30]. These searches were expanded with up to  $36 \text{ fb}^{-1}$  of Run 2 data and their combination, including Run 1 results, yielding an upper limit of  $\mathcal{B}_{H \rightarrow \text{inv}} < 0.26 (0.17^{+0.07}_{-0.05})$  at the 95% CL [31]. A combination from the CMS experiment using a similar dataset reported an observed (expected) upper limit of 0.19 (0.15) [32].

More recently, new direct searches for invisible decays of the Higgs boson using the full Run 2 data of up to  $139 \text{ fb}^{-1}$  were performed, covering most of the Higgs boson production modes, by ATLAS [33–37] and CMS [38–40]. In both experiments the VBF final state is the most sensitive channel resulting in an upper limit of 0.145 (0.103) for ATLAS and 0.18 (0.12) for CMS.

A partial combination of the ATLAS VBF and  $ZH$  searches together with the analyses targeting visible decays of the Higgs boson was carried out [41] and its results reduce the observed (expected) upper limit on  $\mathcal{B}_{H \rightarrow \text{inv}}$  to 0.13 (0.08). Such a combination considers the impact of  $\mathcal{B}_{H \rightarrow \text{inv}}$  on the Higgs boson total decay width and simultaneously determines  $\mathcal{B}_{H \rightarrow \text{inv}}$ , together with the coupling of the Higgs boson to all the SM particles as well as a potential contribution to undetected Higgs boson decays not generating missing transverse energy. The approach relies on a different set of assumptions to what is used in this letter.

This letter presents the statistical combination of all ATLAS direct searches for invisible decays of the Higgs boson using the full Run 2 dataset. This includes the gluon–gluon fusion, VBF,  $ZH$  and  $t\bar{t}H$  production modes, represented in Fig. 1 and assumes the production cross-sections of the Higgs boson does not deviate from the SM predictions [24,42–47]. In addition, a statistical combination with the combined Run 1 result [30] from ATLAS is included, yielding the most sensitive direct constraint to invisible Higgs boson decays in ATLAS.

<sup>1</sup> ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the centre of the detector and the  $z$ -axis along the beam pipe. The  $x$ -axis points to the centre of the LHC ring, and the  $y$ -axis points upward. Cylindrical coordinates  $(r, \phi)$  are used in the transverse plane,  $\phi$  being the azimuthal angle around the  $z$ -axis. The pseudorapidity is defined in terms of the polar angle  $\theta$  as  $\eta = -\ln \tan(\theta/2)$ . The distance between two objects in  $\eta$ – $\phi$  space is  $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$ . Transverse momentum is defined by  $p_T = p \sin\theta$ .

## 2. Combination inputs

The inputs to the combination for the Run 2 result consist of searches for invisible decays of the Higgs boson, with the following production modes:

- VBF topology ( $\text{VBF} + E_T^{\text{miss}}$ ) [33]
- associated production with a  $Z$  boson decaying into electrons or muons ( $Z \rightarrow \ell\ell + E_T^{\text{miss}}$ ) [36]
- associated production with a  $t\bar{t}$  pair, using all top-quark decay modes except those with hadronically decaying  $\tau$ -leptons ( $t\bar{t} + E_T^{\text{miss}}$ ) [48]
- VBF topology in association with an emitted photon ( $\text{VBF} + E_T^{\text{miss}} + \gamma$ ) [34]
- gluon–gluon fusion, in association with a high  $p_T$  jet ( $\text{Jet} + E_T^{\text{miss}}$ ) [37]

all of which use the full data sample, corresponding to an integrated luminosity of  $139 \text{ fb}^{-1}$ .

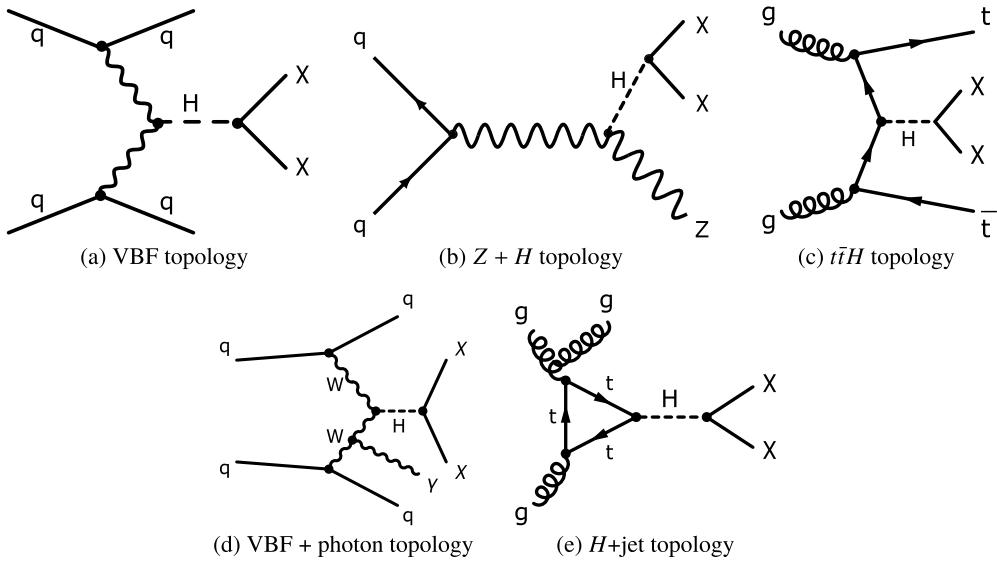

These analyses target different production modes of the Higgs boson and so their event selection criteria are made to be largely orthogonal by using different requirements on lepton, photon, jet and b-tagged jet multiplicity. The level of residual non-orthogonality was evaluated by considering both the data events and signal samples for all the Higgs boson production modes. The largest set of shared events is between the  $\text{Jet} + E_T^{\text{miss}}$  and  $\text{VBF} + E_T^{\text{miss}}$  searches, which select events with large missing transverse energy, no reconstructed leptons, and multiple jets in the final state. The number of overlapping events corresponds to 0.2% (1.5%) of the total data (expected signal Monte Carlo (MC) samples) events selected by the  $\text{Jet} + E_T^{\text{miss}}$  analysis. The impact of the overlap on the final combined result is negligible, altering the upper limit on  $\mathcal{B}_{H \rightarrow \text{inv}}$  by less than 0.001. A brief overview of the Run 2 analyses and the inputs to the Run 1 combined result [30] is given below.

### 2.1. $\text{VBF} + E_T^{\text{miss}}$ search

In the VBF production mode, the  $H \rightarrow$  invisible signal is characterised by two jets with a large separation in pseudorapidity and missing transverse momentum arising from the invisible decays of the Higgs boson. The analysis targeting this signature selects events collected with a trigger selection based on the presence of  $E_T^{\text{miss}}$ . Events are further selected if their two jets with the highest  $p_T$  fulfill the VBF topology requirements: lying in opposite longitudinal hemispheres, being well separated in  $\eta$ , and not back-to-back in the transverse plane. In order to reduce the contribution from  $W$ ,  $Z$ +jets and  $t\bar{t}$  production, and to ensure orthogonality with the other analyses, events containing leptons or photon candidates, or two or more jets identified as b-tagged jets [49] are vetoed.

In this signature, the dominant background sources are  $Z(\nu\nu) + \text{jets}$  and  $W(\ell\nu) + \text{jets}$  production, where in the latter process the charged lepton  $\ell$  is not detected or mis-identified. These backgrounds are evaluated simultaneously using high-statistics control regions in the 1-lepton and 2-leptons channels. A dedicated theoretical calculation at next-to-leading order in the phase space relevant for this analysis [50] allows the estimation of the total irreducible background with a precision of few-percent. The multijet background is directly estimated from data.

The final discrimination is obtained by splitting signal and control region events into 16 bins based on  $E_T^{\text{miss}}$ , the invariant mass of selected dijet pair, their separation in  $\phi$ , and jet multiplicity to maximise the signal/background separation. Assuming the SM cross-section for the VBF production mode, an observed (expected) upper limit of 0.145 (0.103) at the 95% CL is placed on  $\mathcal{B}_{H \rightarrow \text{inv}}$ .

**Fig. 1.** Diagrams illustrating the Higgs boson production mode targeted for the Run 2 searches.

### 2.2. $Z(\rightarrow \ell\ell) + E_T^{\text{miss}}$ search

The search targeting the Higgs boson production in association with a  $Z$  boson selects events containing a pair of electrons or muons and significant missing transverse momentum. The two charged leptons are required to have an invariant mass within a narrow window around the  $Z$  boson mass for the events to satisfy the signal selection requirements.

The dominant backgrounds for this signature are  $ZZ$ , where one of the  $Z$  bosons decays into a neutrino–antineutrino pair, and  $WZ$  production. Contributions from  $t\bar{t}$  and  $WW$  production are estimated from data, using events with two identified different-flavour charged leptons (electrons and muons).

Beyond the signature selections, sensitivity for the  $H \rightarrow$  invisible model is enhanced using a boosted decision tree (BDT) discriminator to improve the separation between signal and background. A profile likelihood fit to the BDT output distribution results in an observed (expected) upper limit on  $\mathcal{B}_{H \rightarrow \text{inv}}$  of 0.185 (0.185) at the 95% CL, assuming the SM production cross-section for this process.

### 2.3. $t\bar{t} + E_T^{\text{miss}}$ search

The production mode of the Higgs boson in association with a top-quark pair is targeted by reinterpreting the combination of several searches for new phenomena in association with heavy flavour quarks [51–53]. The final states arising from this production mode are characterised by the presence of  $b$ -tagged jets and different charged lepton multiplicities, depending on the decay mode of the two  $W$  bosons from the  $t\bar{t}$  decays. In addition, a relevant amount of  $E_T^{\text{miss}}$  is present, coming from the invisible decay products of the Higgs boson and from neutrinos.

A targeted event selection is developed for each lepton multiplicity, resulting in different dominant background contributions from SM processes:  $t\bar{t}$  and  $Z(\rightarrow \nu\nu) + \text{jets}$  in the 0-lepton channel,  $t\bar{t}$  in the 1-lepton channel and  $t\bar{t}Z$  in the 2-lepton channel. For all the combined analyses, background-enriched selections are defined in order to allow the data to aid in estimating the dominant backgrounds, and validation regions are used to verify the robustness of these estimates.

The combination of the three analyses of each lepton multiplicity, considered in this document as a single combined analysis, places an observed (expected) upper limit on  $\mathcal{B}_{H \rightarrow \text{inv}}$  of 0.376

(0.295) at the 95% CL, assuming the SM production cross-section for this process.

### 2.4. $\text{VBF} + E_T^{\text{miss}} + \gamma$ search

The VBF topology is further investigated by a dedicated analysis targeting the final states with an emitted photon. The event signature is characterised by significant missing transverse momentum and one photon in the final state, in addition to a pair of forward jets. In the SM this topology can arise from  $V\gamma + \text{jets}$  production, where  $V$  is either a  $Z$  boson decaying into a neutrino pair or a  $W$  boson decaying leptonically, where the charged lepton is missed. A dense neural network was designed and trained to separate such backgrounds from the  $H \rightarrow$  invisible signal by using kinematic properties of the events. The residual SM contribution to the signal regions is estimated with the aid of specific control regions requiring the presence of electron or muon candidates, to set the normalisation of the MC simulation for  $V\gamma + \text{jets}$  processes. Assuming the SM production cross-section on the signal model, an observed (expected) upper limit on  $\mathcal{B}_{H \rightarrow \text{inv}}$  of 0.375 (0.346) at the 95% CL is evaluated.

### 2.5. Jet + $E_T^{\text{miss}}$ search

The gluon-gluon fusion production mode of the Higgs boson is targeted by a search for new phenomena in events with at least one jet and large missing transverse momentum. Data are collected with a trigger selection based on the presence of  $E_T^{\text{miss}}$  and events are vetoed if any charged lepton or photon is reconstructed. The dominant SM background for this search arises from the irreducible process  $Z \rightarrow \nu\nu$  or  $W \rightarrow \ell\nu$  in association with jets, where the  $W$  boson decays into either hadronically decaying  $\tau$ -leptons or undetected electrons or muons. Additional contributions include  $t\bar{t}$  pair or single-top production, diboson production, and non-collision and multijet backgrounds. The estimate of the major SM processes in the analysis selection is based on a profile likelihood fit to the distribution of the  $p_T$  of the system recoiling against the jets reconstructed in the event, performed simultaneously in the signal region and in orthogonal control regions enriched with the targeted backgrounds. Assuming the SM cross-section for Higgs boson gluon-gluon fusion production, an observed (expected) upper limit on  $\mathcal{B}_{H \rightarrow \text{inv}}$  of 0.329 (0.383) at the 95% CL is achieved.

## 2.6. Run 1 combination

The Run 1 ATLAS  $H \rightarrow$  invisible combination utilises  $4.7 \text{ fb}^{-1}$  of  $pp$  collision data at  $\sqrt{s} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $\sqrt{s} = 8 \text{ TeV}$  [30]. This combination considers inputs from direct detection of  $H \rightarrow$  invisible through Higgs bosons produced via VBF or in association with a vector boson  $V$ , where the vector boson decays either leptonically ( $Z \rightarrow \ell\ell$ ) or hadronically ( $W/Z \rightarrow jj$ ). All of the signal and control regions are utilized in a maximum-likelihood fit resulting in an observed (expected) upper limit of  $\mathcal{B}_{H \rightarrow \text{inv}} < 0.252$  (0.265) at the 95% CL. The sensitivity is driven by the VBF channel.

## 3. Statistical model

The statistical combination of the analyses is performed by constructing the product of their respective likelihoods and maximising the resulting profile likelihood ratio [54]:

$$\Lambda(\beta; \theta) = \frac{L(\hat{\beta}, \hat{\theta}(\beta))}{L(\hat{\beta}, \hat{\theta})}$$

where  $\beta$  and  $\theta$  are the parameter of interest and the nuisance parameters respectively. In the numerator, the nuisance parameters are set to their fitted values  $\hat{\theta}(\beta)$ , which maximise the likelihood function for fixed values of the parameter of interest,  $\beta$ . In the denominator, both the parameter of interest and the nuisance parameters are set to the values  $\hat{\beta}$  and  $\hat{\theta}$  which jointly maximise the likelihood. This is done following the implementation described in Ref. [55,56], with  $\mathcal{B}_{H \rightarrow \text{inv}}$  as the parameter of interest,  $\beta$ . Systematic uncertainties are modelled in the likelihood function as nuisance parameters,  $\theta$ , constrained by Gaussian or log-normal probability density functions. Upper limits on  $\mathcal{B}_{H \rightarrow \text{inv}}$  are determined following the  $CL_s$  formalism [57] using the profile likelihood ratio as a test statistic.

### 3.1. Uncertainty correlation in Run 2 combination

In the combination of Run 2 results, most experimental systematic uncertainties, as well as the uncertainty on the integrated luminosity and the modelling of additional  $pp$  collisions in the same and neighbouring bunch crossings (pile-up), are correlated across all search channels. The assessment of some of the uncertainties associated with the calibration of the jet energy scale (JES) and the jet energy resolution varies between the different analyses in terms of jet reconstruction algorithms and parameterisation choices. For this reason, the uncertainty components stemming from identical methodologies are presumed to be correlated, while the rest of the uncertainties are treated as uncorrelated. Finally, a few experimental systematic uncertainties that are tightly constrained in a given analysis are not correlated in order not to introduce any potential phase space specific biases. The impact of these assumptions on the combined result is estimated by using alternative correlation models and found to have an absolute effect on the  $\mathcal{B}_{H \rightarrow \text{inv}}$  limit of the order of 0.003.

The uncertainties related to background predictions are considered to be uncorrelated among analyses due to the different nature of the leading backgrounds, the variety of kinematic phase space covered by the various analyses, and the usage of data-driven techniques. The systematic uncertainties in the prediction of Higgs boson production follow the recommendations in Ref. [24]. Variations connected to the choice of parton distribution functions (PDF) are considered as correlated among channels while effects of missing

higher-order contributions (estimates through variations of factorisation and renormalisation scales) and parton shower/hadronisation models are considered independently for each Higgs boson production mode and therefore uncorrelated across the analyses.

### 3.2. Uncertainty correlation in Run 1 and Run 2 combination

The Run 2 result described above is combined with the Run 1 searches for  $H \rightarrow$  invisible decays. The adopted correlation scheme follows closely the statistical combination of the partial Run 2 results with the Run 1 combination [31].

The correlation schemes of the individual Run 1 and Run 2 combinations are preserved when combined together. Due to the differences between the detector layouts and data-taking conditions, reconstruction algorithms, which are calibrated using data, and treatment of systematic uncertainties, the correlations between the two LHC runs are not clearly identifiable. Hence, no correlations between Run 1 and 2 are assumed for most instrumental uncertainties. Exceptions are made for uncertainties related to the modelling of the calorimeter response dependence on jet flavour and pile-up, the calibration of the JES across different  $\eta$  regions, and the uncertainties related to the JES of  $b$ -quark jets. Such components are treated as correlated given that the same methodology was applied to compute them in both of the datasets.

Background modelling uncertainties are considered to be uncorrelated in order to reflect improvements in the MC simulation tools and general theory predictions that have evolved significantly since Run 1, both on the side of the hard process simulation and on the side of the parton shower and hadronisation models. For similar reasons, the signal modelling uncertainties are considered uncorrelated between the Run 1 and Run 2 combinations.

The result of the combination shows little sensitivity to the exact correlation scheme between the Run 1 and Run 2 results due to the dominant weight of the latter.

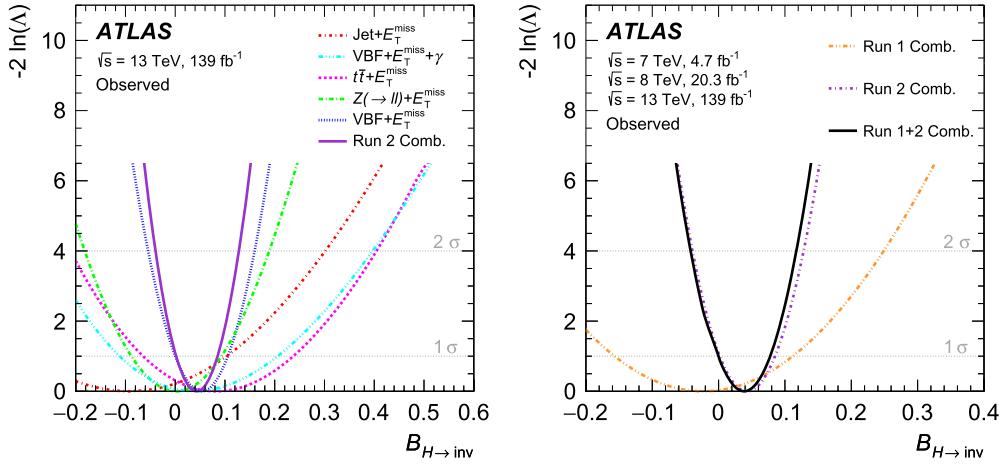

## 4. Results

The value of twice the negative logarithmic profile likelihood ratio  $-2 \ln(\Lambda)(\mathcal{B}_{H \rightarrow \text{inv}}; \theta)$  as a function of  $\mathcal{B}_{H \rightarrow \text{inv}}$  of the individual analyses and of the combined Run 2 result are shown in Fig. 2 (left). The combined best-fit value for  $\mathcal{B}_{H \rightarrow \text{inv}}$  is  $0.04 \pm 0.04$ . Good agreement among the best fit values of the individual analyses, reported in Table 1, is observed.

The best-fit values for  $\mathcal{B}_{H \rightarrow \text{inv}}$  together with the 95% CL expected and observed upper limits for each individual Run 2 analysis and their combination are also shown in Table 1. An upper limit of 0.113 is observed for the combined Run 2 data, while an upper limit of 0.080 was expected in the case of no observed excess in data. Relative to the most sensitive single analysis, the VBF final state, the Run 2 combination brings a relative sensitivity improvement of 22%.

Overall, the leading systematic uncertainty of the result is due to the modelling uncertainties of the  $W/Z + \text{jets}$  prediction in the VBF +  $E_T^{\text{miss}}$  search [33]. Subdominant uncertainties with similar contribution are related to the statistical precision of the data sample; the number of simulated MC events, in particular for the  $W/Z + \text{jets}$  process; the reconstruction and identification of jets and leptons; and the modelling of background processes other than from  $W/Z + \text{jets}$  production.

The observed  $-2 \ln(\Lambda)(\mathcal{B}_{H \rightarrow \text{inv}}; \theta)$  scan of the combined Run 1+2 result is represented in Fig. 2 (right), alongside the individual Run 1 and Run 2 combinations. A best-fit value of  $\mathcal{B}_{H \rightarrow \text{inv}} = 0.04 \pm 0.04$  is obtained for the Run 1+2 combination, corresponding to an observed (expected) upper limit of  $\mathcal{B}_{H \rightarrow \text{inv}} < 0.107$  (0.077) at the 95% CL. The result is dominated by the

**Fig. 2.** The observed value of  $-2 \ln(\Lambda)$  as a function of  $B_{H \rightarrow \text{inv}}$  for the individual Run 2 analyses and their combination (left) and the Run 2 combination together with the Run 1 combination and the total Run 1+2 combination (right).

**Table 1**

Best fit value, observed and expected 95% upper limit on  $B_{H \rightarrow \text{inv}}$  for each individual Run 2 analysis, their combination, the Run 1 combination and the full Run 1+2 combination.

Analysis	Best fit $B_{H \rightarrow \text{inv}}$	Observed 95% U.L.	Expected 95% U.L.
Jet + $E_T^{\text{miss}}$	$-0.09^{+0.19}_{-0.20}$	0.329	$0.383^{+0.157}_{-0.107}$
VBF + $E_T^{\text{miss}} + \gamma$	$0.04^{+0.17}_{-0.15}$	0.375	$0.346^{+0.151}_{-0.097}$
$t\bar{t} + E_T^{\text{miss}}$	$0.08 \pm 0.15$	0.376	$0.295^{+0.125}_{-0.083}$
$Z(\rightarrow \ell\ell) + E_T^{\text{miss}}$	$0.00 \pm 0.09$	0.185	$0.185^{+0.078}_{-0.052}$
VBF + $E_T^{\text{miss}}$	$0.05 \pm 0.05$	0.145	$0.103^{+0.041}_{-0.028}$
Run 2 Comb.	$0.04 \pm 0.04$	0.113	$0.080^{+0.031}_{-0.022}$
Run 1 Comb.	$-0.02^{+0.14}_{-0.13}$	0.252	$0.265^{+0.105}_{-0.074}$
Run 1+2 Comb.	$0.04 \pm 0.04$	0.107	$0.077^{+0.030}_{-0.022}$

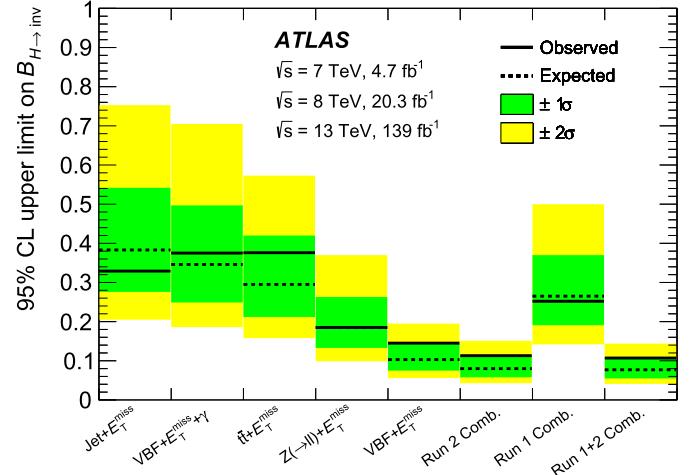

Run 2 analysis with the addition of Run 1 combination improving the expected relative sensitivity by 4%.

The overall picture of the most relevant sources of uncertainty in the Run 1 + Run 2 combination is very similar to that of the Run 2 combination. The upper limit would improve by 50% if all sources of systematic uncertainties were ignored.

The upper limits for each individual Run 2 analysis, their combination, the Run 1 combination and the overall Run 1+2 combined result are summarised in Fig. 3. The current combination improves the constraints on  $B_{H \rightarrow \text{inv}}$  by more than a factor of two as compared to the previous ATLAS combination from Run 1 and partial Run 2 results [31].

## 5. Comparison to direct dark matter detection experiments

The combined observed Run 1+2 upper limit on  $B_{H \rightarrow \text{inv}}$  can be converted into a limit on the spin-independent scattering cross-section of a weakly interacting massive particle (WIMP) and a nucleon [13,18,58,59] ( $\sigma_{\text{WIMP-Nucleon}}$ ), to allow the comparison of the results with the ones from experiments based on different detector technologies. The translation is performed in the context of Higgs portal models [15,60] using an effective field theory framework, where the mediator of new interactions is assumed to be above the TeV-level and therefore well above the scale probed at the Higgs boson mass. The approach assumes that Higgs boson decays into a pair of WIMP particles are kinematically possible ( $m_{\text{WIMP}} < m_H/2$ ) and that the WIMP particle is either a scalar, a

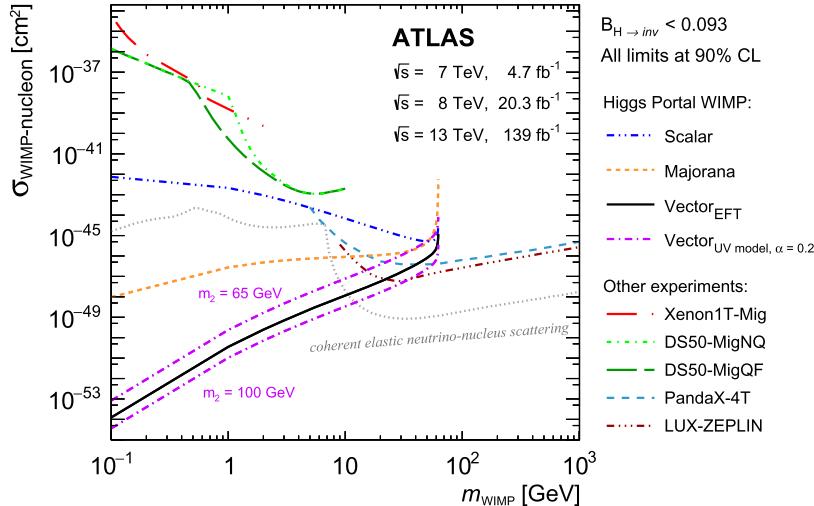

**Fig. 3.** The observed and expected upper limits on  $B_{H \rightarrow \text{inv}}$  at 95% CL for the Run 2 analyses targeting the Jet +  $E_T^{\text{miss}}$ , VBF +  $E_T^{\text{miss}} + \gamma$ ,  $t\bar{t} + E_T^{\text{miss}}$ ,  $Z(\rightarrow \ell\ell) + E_T^{\text{miss}}$ , VBF +  $E_T^{\text{miss}}$  final states and their combination, the Run 1 combination and the full Run 1+2 result; the  $1\sigma$  and  $2\sigma$  contours of the expected limit distribution are also shown.

Majorana fermion, or a vector-like state.<sup>2</sup> In addition, in the case of vectorial DM states, various ultraviolet-complete (UV) models were proposed [62–64]. In such scenarios, the vector DM candidate is introduced as a gauge field of a U(1)' group which extends the SM symmetry group and a dark Higgs sector is added to generate the vector boson mass via the Higgs spontaneous symmetry breaking mechanism. This adds at least two free parameters to the model: the mass  $m_2$  of the additional dark Higgs boson and its mixing angle  $\alpha$  with the SM Higgs boson.

The constraint from the combined observed Run 1+2 exclusion limit of  $B_{H \rightarrow \text{inv}} < 0.093$  at 90% CL is compared to the results from representative direct DM detection experiments [65–68] in Fig. 4. The excluded  $\sigma_{\text{WIMP-Nucleon}}$  values range from  $10^{-45} \text{ cm}^2$  to  $10^{-42} \text{ cm}^2$  in the scalar WIMP scenario. In the Majorana fermion WIMP case, the effective coupling is reduced by a factor  $m_H^2$  [27], excluding cross-section values down to  $2 \times 10^{-47} \text{ cm}^2$  for low WIMP masses;  $\sigma_{\text{WIMP-Nucleon}}$  values down to  $10^{-54} \text{ cm}^2$  can be excluded for the vector WIMP hypothesis. For UV-complete models, Fig. 4 also shows the upper limit cross-section behaviour for a mixing

<sup>2</sup> The value of  $f_N = 0.308 \pm 0.018$  [61] is used as nuclear form factor.

**Fig. 4.** Upper limit at the 90% CL on the spin-independent WIMP-nucleon scattering cross-section as a function of the WIMP mass for direct detection experiments and the interpretation of the  $H \rightarrow$  invisible combination result in the context of Higgs portal models considering scalar, Majorana and vector WIMP hypotheses. For the vector case, results from UV-complete models are shown (pink curves) for two representative values for the mass of the predicted Dark Higgs particle ( $m_2$ ) and a mixing angle  $\alpha=0.2$ . The uncertainties from the nuclear form factor are smaller than the line thickness. Direct detection results are taken from Refs. [65–68]. The neutrino floor for coherent elastic neutrino-nucleus scattering (dotted gray line) is taken from Refs. [69,70], which assume that germanium is the target over the whole WIMP mass range. The regions above the limit contours are excluded in the range shown in the plot.

angle  $\alpha = 0.2$  and for masses of the dark Higgs particle equal to 65 GeV and 100 GeV corresponding to the worst and best limit for a scan of  $m_2$  in the range [65, 1000] GeV [64]. This comparison illustrates the complementarity in coverage by the direct-detection experiments and the searches at colliders, such as the presented analysis.

## 6. Conclusion

In summary, searches for invisible decays of the Higgs boson using  $139 \text{ fb}^{-1}$  of  $pp$  collision data at  $\sqrt{s} = 13 \text{ TeV}$  recorded in Run 2 of the LHC in several Higgs boson production topologies were statistically combined assuming SM Higgs boson production. An upper limit on the invisible Higgs boson branching ratio of  $\mathcal{B}_{H \rightarrow \text{inv}} < 0.113$  ( $0.080^{+0.031}_{-0.022}$ ) is observed (expected) at the 95% CL. A statistical combination of this result with the combination of  $H \rightarrow$  invisible searches using up to  $4.7 \text{ fb}^{-1}$  of  $pp$  collision data at  $\sqrt{s} = 7 \text{ TeV}$  and up to  $20.3 \text{ fb}^{-1}$  at 8 TeV collected in Run 1 of the LHC yields an observed (expected) upper limit of  $\mathcal{B}_{H \rightarrow \text{inv}} < 0.107$  ( $0.077^{+0.030}_{-0.022}$ ) at the 95% CL. The combined Run 1+2 result is translated into upper limits on the WIMP-nucleon scattering cross-section for Higgs portal models. The derived limits on  $\sigma_{\text{WIMP-Nucleon}}$  range down to  $10^{-45} \text{ cm}^2$  (scalar),  $2 \times 10^{-47} \text{ cm}^2$  (Majorana) and  $10^{-54} \text{ cm}^2$  (vector), highlighting the complementarity of DM searches at the LHC and direct detection experiments.

## Declaration of competing interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

## Data availability

The data for this manuscript are not available. The values in the plots and tables associated to this article are stored in HEPDATA (<https://hepdata.cedar.ac.uk>)

## Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWFW and FWF, Austria; ANAS, Azerbaijan; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; ANID, Chile; CAS, MOST and NSFC, China; Minciencias, Colombia; MEYS CR, Czech Republic; DNRF and DNSRC, Denmark; IN2P3-CNRS and CEA-DRF/IRFU, France; SRNSFG, Georgia; BMBF, HGF and MPG, Germany; GSRI, Greece; RGC and Hong Kong SAR, China; ISF and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; NWO, Netherlands; RCN, Norway; MEiN, Poland; FCT, Portugal; MNE/IFA, Romania; MESTD, Serbia; MSSR, Slovakia; ARRS and MIZŠ, Slovenia; DS/ NRF, South Africa; MICINN, Spain; SRC and Wallenberg Foundation, Sweden; SERI, SNSF and Cantons of Bern and Geneva, Switzerland; MOST, Taiwan; TENMAK, Türkiye; STFC, United Kingdom; DOE and NSF, United States of America. In addition, individual groups and members have received support from BCKDF, CANARIE, Compute Canada and CRC, Canada; PRIMUS 21/SCI/017 and UNCE SCI/013, Czech Republic; COST, ERC, ERDF, Horizon 2020 and Marie Skłodowska-Curie Actions, European Union; Investissements d'Avenir Labex, Investissements d'Avenir Idex and ANR, France; DFG and AvH Foundation, Germany; Herakleitos, Thales and Aristeia programmes co-financed by EU-ESF and the Greek NSRF, Greece; BSF-NSF and MINERVA, Israel; Norwegian Financial Mechanism 2014–2021, Norway; NCN and NAWA, Poland; La Caixa Banking Foundation, CERCA Programme Generalitat de Catalunya and PROMETEO and GenT Programmes Generalitat Valenciana, Spain; Göran Gustafssons Stiftelse, Sweden; The Royal Society and Leverhulme Trust, United Kingdom.

The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN, the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA), the Tier-2 facilities worldwide and large non-WLCG resource providers. Major contributors of computing resources are listed in Ref. [71].

<sup>170</sup> Fakultät für Mathematik und Naturwissenschaften, Fachgruppe Physik, Bergische Universität Wuppertal, Wuppertal; Germany  
<sup>171</sup> Department of Physics, Yale University, New Haven CT; United States of America

<sup>a</sup> Also Affiliated with an institute covered by a cooperation agreement with CERN.

<sup>b</sup> Also at Borough of Manhattan Community College, City University of New York, New York NY; United States of America.

<sup>c</sup> Also at Bruno Kessler Foundation, Trento; Italy.

<sup>d</sup> Also at Center for High Energy Physics, Peking University; China.

<sup>e</sup> Also at Center for Interdisciplinary Research and Innovation (CIRI-AUTH), Thessaloniki ; Greece.

<sup>f</sup> Also at Centro Studi e Ricerche Enrico Fermi; Italy.

<sup>g</sup> Also at CERN, Geneva; Switzerland.

<sup>h</sup> Also at Département de Physique Nucléaire et Corpusculaire, Université de Genève, Genève; Switzerland.

<sup>i</sup> Also at Departament de Fisica de la Universitat Autònoma de Barcelona, Barcelona; Spain.

<sup>j</sup> Also at Department of Financial and Management Engineering, University of the Aegean, Chios; Greece.

<sup>k</sup> Also at Department of Physics and Astronomy, Michigan State University, East Lansing MI; United States of America.

<sup>l</sup> Also at Department of Physics, California State University, East Bay; United States of America.

<sup>m</sup> Also at Department of Physics, California State University, Sacramento; United States of America.

<sup>n</sup> Also at Department of Physics, King's College London, London; United Kingdom.

<sup>o</sup> Also at Department of Physics, University of Fribourg, Fribourg; Switzerland.

<sup>p</sup> Also at Department of Physics, University of Thessaly; Greece.

<sup>q</sup> Also at Department of Physics, Westmont College, Santa Barbara; United States of America.

<sup>r</sup> Also at Hellenic Open University, Patras; Greece.

<sup>s</sup> Also at Institut Catalana de Recerca i Estudis Avancats, ICREA, Barcelona; Spain.

<sup>t</sup> Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg; Germany.

<sup>u</sup> Also at Institute of Applied Physics, Mohammed VI Polytechnic University, Ben Guerir; Morocco.

<sup>v</sup> Also at Institute of Particle Physics (IPP); Canada.

<sup>w</sup> Also at Institute of Physics and Technology, Ulaanbaatar; Mongolia.

<sup>x</sup> Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku; Azerbaijan.

<sup>y</sup> Also at Institute of Theoretical Physics, Ilia State University, Tbilisi; Georgia.

<sup>z</sup> Also at Lawrence Livermore National Laboratory, Livermore; United States of America.

<sup>aa</sup> Also at The Collaborative Innovation Center of Quantum Matter (CICQM), Beijing; China.

<sup>ab</sup> Also at TRIUMF, Vancouver BC; Canada.

<sup>ac</sup> Also at Università di Napoli Parthenope, Napoli; Italy.

<sup>ad</sup> Also at University of Colorado Boulder, Department of Physics, Colorado; United States of America.

<sup>ae</sup> Also at Washington College, Maryland; United States of America.

<sup>af</sup> Also at Physics Department, An-Najah National University, Nablus; Palestine.

\* Deceased.
