**Abstract** The simultaneous intercalation of protons and Zn<sup>2+</sup> ions in aqueous electrolytes presents a significant obstacle to the widespread adoption of aqueous zinc ion batteries (AZIBs) for large-scale use, a challenge that has yet to be overcome. To address this, we have developed a MnO<sub>2</sub>/tetramethylammonium (TMA) superstructure with an enlarged interlayer spacing, designed specifically to control H<sup>+</sup>/Zn<sup>2+</sup> co-intercalation in AZIBs. Within this superstructure, the pre-intercalated TMA<sup>+</sup> ions work as spacers to stabilize the layered structure of MnO<sub>2</sub> cathodes and expand the interlayer spacing substantially by 28% to 0.92 nm. Evidence from *in operando* pH measurements, *in operando* synchrotron X-ray diffraction, and X-ray absorption spectroscopy shows that the enlarged interlayer spacing facilitates the diffusion and intercalation of Zn<sup>2+</sup> ions (which have a large ionic radius) into the MnO<sub>2</sub> cathodes. This spacing also helps suppress the competing H<sup>+</sup> intercalation and the formation of detrimental Zn<sub>4</sub>(OH)<sub>6</sub>SO<sub>4</sub>·5H<sub>2</sub>O, thereby enhancing the structural stability of MnO<sub>2</sub>. As a result, enhanced Zn<sup>2+</sup> storage properties, including excellent capacity and long cycle stability, are achieved.

**Keywords:** aqueous zinc ion batteries, MnO<sub>2</sub>, superstructure, *in operando* synchrotron diffraction, X-ray absorption spectroscopy

## Introduction

Recently, aqueous zinc ion batteries (AZIBs) with mildly acidic electrolytes are gaining considerable attention for large-scale energy storage due to the high theoretical capacity of the zinc metal anode, as well as their environmental friendliness, easy fabrication, and low cost.<sup>1-3</sup> Meanwhile, manganese oxide ( $\text{MnO}_2$ ) materials are particularly desirable for use as cathodes for AZIBs due to their high working voltage, high specific capacity, abundance, affordability, easy processing, and eco-friendliness.<sup>4</sup> Despite this, recent studies have demonstrated that a significant amount of  $\text{H}^+/\text{Zn}^{2+}$  co-insertion occurs when  $\text{MnO}_2$  cathodes are cycled using inexpensive  $\text{ZnSO}_4$  electrolytes, which are the electrolytes of choice for large-scale energy storage applications.<sup>5-13</sup> The intercalation of  $\text{H}^+$  in mildly acidic aqueous  $\text{ZnSO}_4$  electrolytes (i.e. 2 M  $\text{ZnSO}_4$ ,  $\text{pH} \approx 4$ ) induces the formation of  $\text{Zn}_4(\text{OH})_6\text{SO}_4 \cdot x\text{H}_2\text{O}$  (ZHS). This process leads to the formation of an insulating layer on the electrode surface, which then detaches from the electrode during cycling, leading to active material loss and eventual cell failure.<sup>14-16</sup> Moreover, because the concentration of  $\text{H}^+$  is much lower than that of  $\text{Zn}^{2+}$  in the mildly acidic aqueous electrolytes, the intercalation of  $\text{H}^+$  promotes disassociation of water in electrolytes<sup>17-20</sup> and induces the collapse of the  $\text{MnO}_2$  host lattice during repeated cycling.<sup>21</sup> Therefore, controlling the  $\text{H}^+/\text{Zn}^{2+}$  co-intercalation in aqueous media is vital for developing high-performance cathode materials in AZIBs.

Limited approaches have been reported to mitigate the detrimental  $\text{H}^+$  intercalation and enhance  $\text{Zn}^{2+}$  intercalation in aqueous electrolytes.<sup>22</sup> Important advances in this direction include regulating water activity<sup>15</sup>, tuning the zinc ion solvation structure<sup>14</sup>, and subfreezing the batteries<sup>22</sup>, etc. The interlayer spacing of  $\text{MnO}_2$  is expected to be a critical factor in the competition between  $\text{Zn}^{2+}$  and  $\text{H}^+$  intercalation at the interface of  $\text{MnO}_2$ , due to their distinct differences in ionic radius. Compared to  $\text{H}^+$ , the ionic radius and atomic weight of  $\text{Zn}^{2+}$  are larger, resulting in slower kinetics for  $\text{Zn}^{2+}$  intercalation.<sup>23-26</sup> To effectively address the issue of low  $\text{Zn}^{2+}$  diffusion and intercalation rates in  $\text{MnO}_2$  cathodes, it is essential to provide enough space to accommodate  $\text{Zn}^{2+}$  and its solvation sheath (approximately. 0.86 nm),<sup>27</sup> a challenge that remains.

Herein, we demonstrate a  $\text{MnO}_2$ /tetramethylammonium (TMA) superstructure (TMA- $\text{MnO}_2$ ) with an enlarged interlayer spacing as a stable cathode for AZIBs. In the

1  
2  
3  
4 superstructure, the pre-intercalated TMA cations act as spacers to stabilize the layered  
5 structure of the MnO<sub>2</sub> and substantially expand the interlayer spacing to 0.92 nm, which  
6 facilitates the diffusion of Zn<sup>2+</sup> in the MnO<sub>2</sub> cathode and increases the number of active  
7 sites. *In operando* techniques including pH characterizations, synchrotron X-ray  
8 diffraction and X-ray absorption spectroscopy (XAS) were performed to study the energy  
9 storage mechanism of TMA-MnO<sub>2</sub> during cycling. These studies show that the enlarged  
10 interlayer spacing can effectively enhance the intercalation of Zn<sup>2+</sup> and restrict the  
11 competing H<sup>+</sup> intercalation, which helps suppress the concomitant deposition of ZHS and  
12 improve the structure stability of MnO<sub>2</sub>. As a result, the TMA-MnO<sub>2</sub> superstructure  
13 cathode exhibits enhanced charge-discharge performance, including excellent capacity and  
14 long cycle stability, holding great promise for the development of advanced cathode  
15 materials in AZIBs.  
16

## 26 **2. Experimental section**

### 27 *2.1. Materials*

30  
31 KMnO<sub>4</sub> (Analytical Reagent (AR), 99.5%), and H<sub>2</sub>SO<sub>4</sub> (AR, 98%) were purchased  
32 from Beijing Chemical Works. N(CH<sub>3</sub>)<sub>4</sub>Cl (99%) was purchased from Innochem. Super P  
33 was obtained from Sigma-Aldrich. Polyvinylidene difluoride (PVDF) (Solef® 5130) was  
34 purchased from Arkema. CH<sub>3</sub>OH (AR, 99.5%), CH<sub>3</sub>CH<sub>2</sub>OH (AR, 97%), ZnSO<sub>4</sub>·7H<sub>2</sub>O (AR,  
35 99.7%), MnSO<sub>4</sub>·H<sub>2</sub>O (AR, 99%), and N-Methyl-2-pyrrolidone (NMP) (AR, 99.9%) were  
36 purchased from Aladdin. All chemicals and solvents were used as received.  
37  
38  
39  
40  
41

### 42 *2.2. Synthesis of materials*

43  
44 ***Synthesis of MnO<sub>2</sub>***: A mixture of KMnO<sub>4</sub> (0.75 mmol), H<sub>2</sub>SO<sub>4</sub> (0.75 mmol), and  
45 CH<sub>3</sub>OH (15 mmol) was combined in 500 mL of water and stirred for 10 minutes. The  
46 solution was then heated at 95°C for 1 hour, resulting in the formation of a MnO<sub>2</sub> nanosheet  
47 suspension. The pristine MnO<sub>2</sub> material was isolated through centrifugation, followed by  
48 multiple washes with deionized water and ethanol. It was subsequently dried at 60°C under  
49 vacuum for 12 hours.  
50  
51

52 ***Synthesis of TMA-MnO<sub>2</sub>***: To the aforementioned MnO<sub>2</sub> nanosheet suspension, a 0.5 M  
53 solution of tetramethylammonium chloride (TMA, 50 mL) was added and stirred for 1 hour.  
54 The precipitate was separated via centrifugation and washed repeatedly with deionized  
55  
56

2  
3  
4 water and ethanol. The TMA-MnO<sub>2</sub> product was then dried at 60°C under vacuum for 12  
5  
6 hours.

### 7 8 2.3. Material Characterization 9

10 The X-ray diffraction (XRD) patterns of MnO<sub>2</sub> were collected using a Bruker D8  
11 equipped with Cu K $\alpha$ -radiation. The scanning electron microscopy (SEM) and energy  
12 dispersive spectroscopy (EDS) analyses were performed on a Hitachi Regulus8100. A  
13 JEM-2200FS from JEOL was used for transmission electron microscopy (TEM)  
14 measurement. X-ray photoelectron spectroscopy (XPS) was recorded using a Thermo  
15 Scientific NEXSA. Fourier-transform infrared spectroscopy (FTIR) was performed using  
16 a VERTEX 80V. Thermogravimetric analysis (TGA) was measured with a STA 449F3  
17 from NETZSCH in an air atmosphere. The *in operando* pH values were measured with a  
18 Mettler Toledo-FE28 equipped with an Inlab microprobe.

### 28 2.4. Electrochemical Measurements 29

30 The 2032-type coin cells were assembled with MnO<sub>2</sub>/TMA-MnO<sub>2</sub> as the cathode, Zn  
31 foil as the anode, and a 2 M ZnSO<sub>4</sub> + 0.2 M MnSO<sub>4</sub> aqueous solution as the electrolyte.  
32 The initial pH of the electrolyte was adjusted to around 5.1 using a trace amount of ZnO.  
33 The cathodes were prepared by mixing the MnO<sub>2</sub>/TMA-MnO<sub>2</sub> (60 wt%), Super P (30 wt%),  
34 and PVDF (10 wt%) with NMP to form a slurry, which was then cast on the titanium foil.  
35 The mass loading of active materials was approximately 1.2 mg cm<sup>-2</sup>. The cyclic  
36 voltammetry (CV) tests were performed on a Bio-Logic VSP multichannel electrochemical  
37 workstation. The galvanostatic charge/discharge curves (GCD), cycling performance, and  
38 galvanostatic intermittent titration technique (GITT) were measured using a LAND-2010  
39 automatic battery tester. The three-electrode test was carried out with a carbon rod as the  
40 counter electrode, Ag/AgCl as the reference electrode, and MnO<sub>2</sub>/TMA-MnO<sub>2</sub> as the  
41 working electrode.

### 52 2.5 *In operando* synchrotron-based experiments 53

54 A modified 2025-type coin cell was used with a 5-mm hole in the center of both the  
55 cathode and anode. The mass loading of MnO<sub>2</sub> in the cathode was ~5.0 mg·cm<sup>-2</sup>. *In*  
56 *operando* synchrotron diffraction was performed using synchrotron radiation ( $\lambda=0.20734$   
57 Å, 60 keV) at the P02.1 beamline PETRA, DESY in Hamburg. Current densities of 20 mA

4  $\text{g}^{-1}$  for  $\text{MnO}_2$  and  $25 \text{ mA g}^{-1}$  for TMA- $\text{MnO}_2$  were used for the first cycles between 1.8 V  
5 and 0.8 V and also for *in operando* X-ray absorption spectroscopy (XAS) at the P65  
6 beamline at PETRA. The Mn K-edge XAS spectra were recorded in quick-XAS (5  
7 min/spectrum) mode in fluorescence geometry using a passivated implanted planar silicon  
8 (PIPS) diode detector. The Mn K-edges for  $\text{MnO}_2$  and TMA- $\text{MnO}_2$  were measured during  
9 electrochemical cycling, and the energies were calibrated using a Mn foil as commonly  
10 employed in XAS experiments.  $\text{MnO}_2$ ,  $\text{Mn}_2\text{O}_3$ , and MnO were used as standard materials.  
11 All the XAS data were collected at room temperature with a Si(111) double-crystal  
12 monochromator, and all the XAS spectra were analyzed and processed utilizing the  
13 DEMETER software package.

### 22 *2.6 In operando pH measurement*

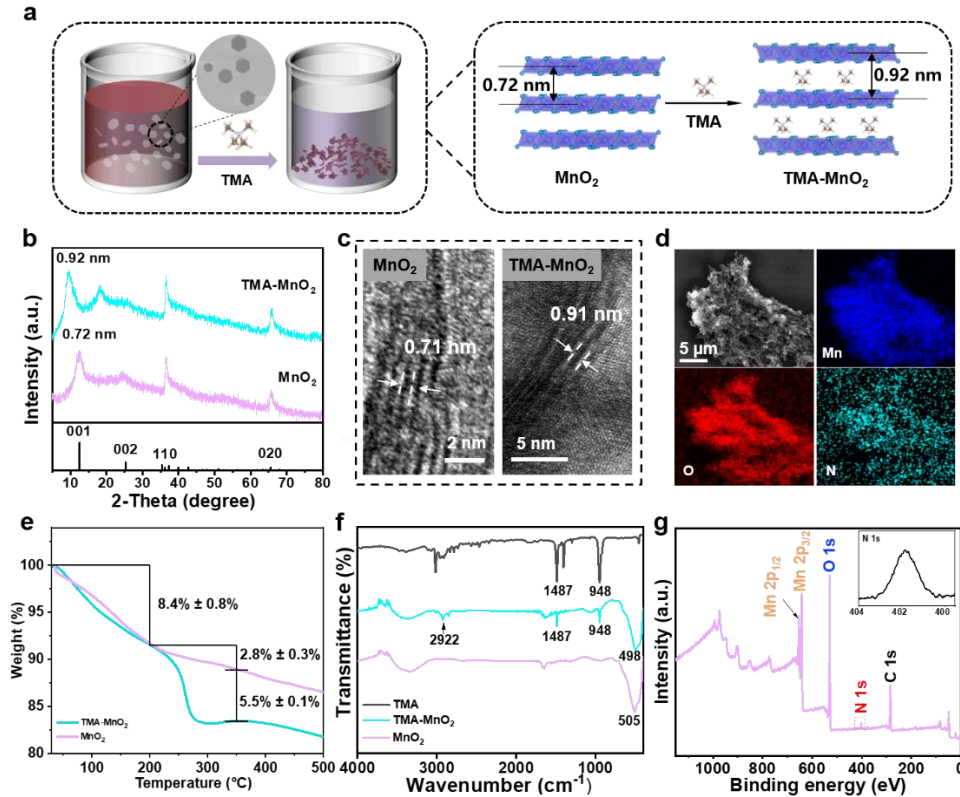

23  
24 The pH evolution on the cathode region was measured with an H-type cell, as shown in  
25 **Figure S6**. The Zn anode and cathode with the same size of  $2.5 \text{ cm} \times 3.5 \text{ cm}$  were placed  
26 at opposite sides of an H-cell. Then the 2 M  $\text{ZnSO}_4$  + 0.2 M  $\text{MnSO}_4$  aqueous electrolyte  
27 was added. The micro probe of the pH meter was then placed near to the cathode region.  
28 In-situ pH tests were carried out with a current density of  $100 \text{ mA g}^{-1}$  between 1.8 V and  
29 0.8 V.

## 37 **3. Results and Discussion**

38  
39  
40 The TMA- $\text{MnO}_2$  material was prepared by a bottom-up self-assembly of  $\text{MnO}_2$   
41 nanosheets and TMA cations, as illustrated in **Figure 1a**. The effect of TMA pre-  
42 intercalation on the crystal structure and layer spacing was demonstrated by XRD (**Figure**  
43 **1b**). The strongest reflections of pristine  $\text{MnO}_2$  can be found at  $12.3^\circ$ ,  $24.8^\circ$ ,  $36.6^\circ$ , and  
44  $65.7^\circ$ , which are indexed to the (001), (002), (110), and (020) planes of layered birnessite  
45  $\text{MnO}_2$  ( $\text{K}_{0.46}\text{Mn}_2\text{O}_4 \cdot (\text{H}_2\text{O})_{1.6}$ , JCPDS: 01-080-1098) with  $C2/m$  symmetry and lattice  
46 parameters of  $a = 5.15 \text{ \AA}$ ,  $b = 2.84 \text{ \AA}$ ,  $c = 7.18 \text{ \AA}$ , and  $\beta = 100.76^\circ$ . For TMA- $\text{MnO}_2$ , the  
47 corresponding reflections are located at  $9.8^\circ$ ,  $18.3^\circ$ ,  $36.6^\circ$ , and  $65.7^\circ$ . Notably, the Bragg  
48 reflection 001 shifts from  $12.3^\circ$  to  $9.8^\circ$ , corresponding to an expansion of the interlayer  
49 spacing in the c-axis direction from 0.72 nm to 0.92 nm, which indicates that TMA was  
50 uniformly intercalated into the interlayer of  $\text{MnO}_2$ , forming a superstructure. The enlarged  
51

1  
2  
3  
4 interlayer spacing enhances ionic conductivity and supports the (de)insertion of  $\text{Zn}^{2+}$  ions,  
5 further improving the storage capacity of  $\text{MnO}_2$ , as demonstrated in the subsequent sections.  
6 Moreover, after TMA intercalation, the 110 and 020 reflections show no shift with respect  
7 to pristine  $\text{MnO}_2$ , indicating that the in-plane lattices of  $\text{MnO}_2$  remain unchanged. The  
8 morphology and interlayer spacing of both pristine  $\text{MnO}_2$  and TMA- $\text{MnO}_2$  were further  
9 characterized by SEM and HRTEM (**Figure S1**). As indicated in **Figure S2**, the SEM  
10 images of both TMA- $\text{MnO}_2$  and pristine  $\text{MnO}_2$  exhibit a distinctive nano-flower  
11 morphology, which is assembled from two-dimensional nanosheets. This nano-flower  
12 structure is notable because it provides a high surface area and facilitates efficient ion  
13 transport. As shown in **Figure 1c**, the measured interlayer spacing of TMA- $\text{MnO}_2$  in the  
14 HRTEM image is 0.91 nm, which is 0.20 nm larger than that of pristine  $\text{MnO}_2$  (0.71 nm).  
15 Both spacing values align well with the XRD results, further validating the successful  
16 intercalation of TMA into the interlayer of  $\text{MnO}_2$  and the consequent enlargement of the  
17 interlayer spacing. TGA and FTIR spectra were then carried out to further understand the  
18 detailed structure of TMA- $\text{MnO}_2$ . As shown in the TGA curves (**Figure 1e**), the weight  
19 loss before 200°C is attributed to the removal of physically absorbed water, while the  
20 weight loss between 200 to 350°C results from the thermal decomposition of TMA and  
21 structural water. Based on the different pyrolysis temperatures of the components, the  
22 weight ratio of TMA in TMA- $\text{MnO}_2$  is identified as ~5.5%. The FTIR spectra for TMA,  
23 pristine  $\text{MnO}_2$ , and TMA- $\text{MnO}_2$  are shown in **Figure 1f**. The characteristic peak of Mn-O  
24 stretching vibration is observed in both pristine  $\text{MnO}_2$  (505  $\text{cm}^{-1}$ ) and TAM- $\text{MnO}_2$  (498  
25  $\text{cm}^{-1}$ ). In addition, the characteristic vibration peaks<sup>28</sup> of  $\text{C}_4\text{N}$  at 948  $\text{cm}^{-1}$ ,  $\text{CH}_3$  group at  
26 1487  $\text{cm}^{-1}$ , and C-H at 2922  $\text{cm}^{-1}$  are found in TMA- $\text{MnO}_2$ , suggesting the existence of  
27 TMA in the material. Furthermore, the elemental composition of TMA- $\text{MnO}_2$  was studied  
28 by XPS and EDS. As shown in the XPS spectra (**Figure 1g**), besides Mn and O, the unique  
29 N element from TMA is observed in TMA- $\text{MnO}_2$ . The N 1s XPS located at 401.83 eV  
30 originates from the ammonium group in TMA. Both Mn 3s and Mn 2p XPS spectra indicate  
31 a slight reduction in the Mn valence state induced by  $\text{TMA}^+$  intercalation (**Figure S3a-b**).  
32 Meanwhile, the O 1s XPS spectra show a reduction in the crystalline water content in  
33 TMA- $\text{MnO}_2$  (**Figure S3c**). The EDS mapping images show that N, Mn, and O elements

are uniformly dispersed in the TMA-MnO<sub>2</sub> nanosheets, indicating the homogeneous distribution of TMA (**Figure 1d**).

**Figure 1.** **a**), Schematic illustration of the preparation of TMA-MnO<sub>2</sub>; **b**), XRD patterns of MnO<sub>2</sub> and TMA-MnO<sub>2</sub> (Cu Kα); **c**), HRTEM images of MnO<sub>2</sub> and TMA-MnO<sub>2</sub>; **d**), SEM image and the corresponding EDS mapping of TMA-MnO<sub>2</sub>; **e**), TGA of the TMA-MnO<sub>2</sub> and MnO<sub>2</sub>. The error estimates are provided based on the precision of one experiment; **f**), FTIR spectra of TMA, MnO<sub>2</sub>, and TMA-MnO<sub>2</sub>; **g**), The XPS spectra of TMA-MnO<sub>2</sub> and the corresponding high-resolution N 1s (inset).

The electrochemical performance of TMA-MnO<sub>2</sub> and MnO<sub>2</sub> cathodes in AZIBs was studied with coin cells using a 2 M ZnSO<sub>4</sub> + 0.2 M MnSO<sub>4</sub> aqueous electrolyte. The first three CV curves were collected at a scan rate of 0.27 mV s<sup>-1</sup> (equivalent to 1 C) over the voltage range of 0.8 V to 1.8 V (**Figure 2a-b**). Two pairs of redox peaks are observed for both TMA-MnO<sub>2</sub> and MnO<sub>2</sub> in AZIBs, indicating that both materials undergo a two-step electrochemical process. Irreversible processes are observed in the first cycle for both cathodes. In subsequent cycles, the CV curves retain their shapes, demonstrating the good reversibility of the redox reactions. Notably, compared to MnO<sub>2</sub>, TMA-MnO<sub>2</sub> shows a

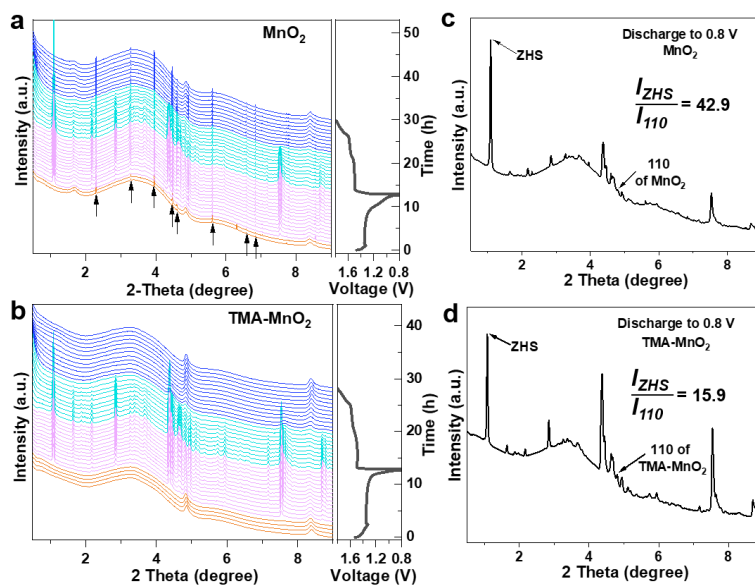

1  
2  
3  
4 lower overpotential (0.292 V vs 0.330 V). Furthermore, the sharper oxidation peak and  
5 high current response in TMA-MnO<sub>2</sub> compared to MnO<sub>2</sub> indicates a faster ion migration  
6 rate within the TMA-MnO<sub>2</sub> structure. The pre-embedding of TMA<sup>+</sup> ions into the interlayers  
7 of MnO<sub>2</sub> enhances the reaction kinetics by improving ion diffusion pathways. The  
8 enhanced ion diffusion coefficient for the TMA-MnO<sub>2</sub> electrodes was further confirmed  
9 by GITT (**Figure S4**). EIS spectra also imply that the TMA-MnO<sub>2</sub> electrode possesses a  
10 lower interface charge transfer resistance (**Figure S5**). **Figure 2c** presents the rate  
11 performance of the TMA-MnO<sub>2</sub> and MnO<sub>2</sub> cathodes. As the current density increases, the  
12 specific capacity decreases for both cathodes. At a low current density of 0.05 A g<sup>-1</sup>, the  
13 TMA-MnO<sub>2</sub> cathode exhibits an average capacity of 319 mAh g<sup>-1</sup>. When the current  
14 density increases to 3 A g<sup>-1</sup>, a specific capacity of 136 mAh g<sup>-1</sup> is retained. In contrast, the  
15 MnO<sub>2</sub> cathode only delivers an average capacity of 230 mAh g<sup>-1</sup> at 0.05 A g<sup>-1</sup> and 129 mAh  
16 g<sup>-1</sup> at 3 A g<sup>-1</sup>. Note that TMA-MnO<sub>2</sub> shows a larger capacity decrease as the current density  
17 increases. This might suggest that under high current density, the dominant inserted ion  
18 type changes, resulting in a significant reduction in the capacity. A more detailed  
19 discussion of the energy storage mechanism is presented in the following sections. GCD  
20 tests were performed to investigate the cycling stability of the cells. As shown in **Figure**  
21 **2d**, the TMA-MnO<sub>2</sub> cell exhibits a discharge capacity of 298 mAh g<sup>-1</sup> at 0.5 A g<sup>-1</sup>, which  
22 is 1.3 times larger than that of MnO<sub>2</sub> (222 mAh g<sup>-1</sup>). After 200 cycles, the specific capacity  
23 for TMA-MnO<sub>2</sub> can still reach 263 mAh g<sup>-1</sup> with 88% capacity retention, which is more  
24 stable than that of MnO<sub>2</sub> (**Figure 2e**). In addition, the TMA-MnO<sub>2</sub> cell still performs  
25 excellently at a high current density of 1 A g<sup>-1</sup>, maintaining 205 mAh g<sup>-1</sup> after 500 cycles  
26 (**Figure 2f**). In contrast, the capacity of MnO<sub>2</sub> quickly drops to 60 mAh g<sup>-1</sup> after 500 cycles.  
27 TMA-MnO<sub>2</sub> exhibits higher capacity, better rate performance, and a more stable cycling  
28 life compared with recently reported Zn||MnO<sub>2</sub> batteries (**Table S1**).<sup>29-42</sup>

*In operando* synchrotron diffraction was performed to illustrate the phase evolution of TMA-MnO<sub>2</sub> and MnO<sub>2</sub> during the discharge/charge processes (**Figure 3**). For the MnO<sub>2</sub> electrode, the synchrotron diffraction patterns show reflections at 1.67°, 4.85°, and 8.40°. These reflections correspond to the (001), (110), and (020) crystal planes of MnO<sub>2</sub> respectively, similar to what is typically observed in XRD spectra. For the TMA-MnO<sub>2</sub> electrode, synchrotron diffraction patterns display reflections at 4.86° and 8.41°, corresponding to the (110) and (020) crystal planes. Bragg reflections at 1.08°, 1.66°, 4.35°, 4.83°, 7.53°, and 8.37° are observed for both MnO<sub>2</sub> and TMA-MnO<sub>2</sub> during discharging to 0.8 V. These reflections correspond to the formation of the Zn<sub>4</sub>(OH)<sub>6</sub>SO<sub>4</sub>·5H<sub>2</sub>O by-product (ZHS, JCPDS No. 78-0246) with space group  $P\bar{1}$  and lattice parameters  $a = 8.354 \text{ \AA}$ ,  $b = 8.350 \text{ \AA}$ ,  $c = 11.001 \text{ \AA}$ , and  $\alpha = 94.41^\circ$ ,  $\beta = 82.95^\circ$ ,  $\gamma = 119.93^\circ$ . Especially, the 001

1  
2  
3  
4 reflection, with a large interplanar spacing of  $\sim 11 \text{ \AA}$ , exhibits extremely high intensity at  
5  
6 the end of discharge, suggesting a preferential growth of ZHS byproduct along [001]  
7  
8 direction. After charging back to 1.8 V, the ZHS reflections completely disappear. Note  
9  
10 that the Bragg reflections of  $\text{MnO}_2$  are well maintained throughout the initial  
11  
12 discharge/charge cycle, indicating the structural robustness. For both electrodes, no  
13  
14 reflections of spinel  $\text{ZnMn}_2\text{O}_4$  or  $\text{MnOOH}$  can be observed, which indicates the good  
15  
16 structure stability of the  $\text{MnO}_2$  and TMA- $\text{MnO}_2$  cathodes. Generally, the insertion of  $\text{H}^+$   
17  
18 into the cathode could increase the pH at the cathode region, resulting in ZHS  
19  
20 precipitation.<sup>10,16</sup> Interestingly, the formation of ZHS appears later for TMA- $\text{MnO}_2$  than  
21  
22 for  $\text{MnO}_2$  electrodes, suggesting that less  $\text{H}^+$  is inserted into TMA- $\text{MnO}_2$  than into  $\text{MnO}_2$   
23  
24 during the first discharge. Moreover, a smaller amount of ZHS is formed on the TMA-  
25  
26  $\text{MnO}_2$  electrode than on the  $\text{MnO}_2$  electrode at the fully discharged state of 0.8 V, as  
27  
28 concluded from the much lower intensity of the ZHS 001 reflection relative to the cathode  
29  
30 reflections (**Figure 3c-d**).

4 To further explore the ion intercalation mechanisms of MnO<sub>2</sub> and TMA-MnO<sub>2</sub>, *in*  
5 *operando* pH changes at the cathode interface-near region of AZIB using the 2 M ZnSO<sub>4</sub>  
6 + 0.2 M MnSO<sub>4</sub> electrolyte were measured (**Figure 4a-b and S6**). During the discharge  
7 process, the pH value at the MnO<sub>2</sub> electrode surface increases gradually (**Figure 4a**),  
8 indicating that H<sup>+</sup> ions insert into the cathode, thus leading to a decrease of the H<sup>+</sup>  
9 concentration at the cathode interface-near region. Notably, a sudden drop of pH from 5.26  
10 to 5.10 happens at the beginning of the charge, indicating some H<sup>+</sup> ions are extracted from  
11 the discharged cathode. During the subsequent charging process, the pH value at the  
12 cathode region decreases gradually, indicating the continuous H<sup>+</sup> release from the cathode.  
13 Interestingly, a different pH change behavior is observed for the TMA-MnO<sub>2</sub> electrode. As  
14 shown in **Figure 4b**, during the discharge process, the pH value at the TMA-MnO<sub>2</sub>  
15 electrode region initially decreases, then increases. A sudden pH increase is observed at  
16 the beginning of the charging process, suggesting that much fewer H<sup>+</sup> ions are released  
17 from the cathode compared to the MnO<sub>2</sub> electrode. During the further charging process, the  
18 pH value at the TMA-MnO<sub>2</sub> electrode region shows a decrease-increase-decrease pattern.  
19 These fluctuations in pH value for TMA-MnO<sub>2</sub> during the discharge and charge process  
20 are probably related to the more competitive Zn<sup>2+</sup> (de)intercalation. Compared to the MnO<sub>2</sub>  
21 electrode, the TMA-MnO<sub>2</sub> electrode exhibits a smaller total decrease in pH value during  
22 the charging process, providing further evidence of reduced H<sup>+</sup> release from the TMA-  
23 MnO<sub>2</sub> electrode.

41 To further confirm the promoted Zn<sup>2+</sup> insertion mechanism, the electrochemical  
42 behaviors of the MnO<sub>2</sub> and TMA-MnO<sub>2</sub> electrodes were compared in 0.2 M MnSO<sub>4</sub>  
43 electrolytes with or without 2 M Zn<sup>2+</sup> using the three-electrode cells, as shown in **Figure**  
44 **4c**. The TMA-MnO<sub>2</sub> electrode in the Zn<sup>2+</sup> containing electrolyte shows a larger discharge  
45 capacity of 286 mAh g<sup>-1</sup> at 0.1 A g<sup>-1</sup> compared to MnO<sub>2</sub> (237 mAh g<sup>-1</sup>), aligning with  
46 observations from two-electrode coin cells (**Figure 2c**). In the electrolyte without Zn<sup>2+</sup>, the  
47 discharge capacities of TMA-MnO<sub>2</sub> and MnO<sub>2</sub> decrease to 210 and 208 mAh g<sup>-1</sup>,  
48 respectively, indicating that H<sup>+</sup> insertion takes place. The TMA-MnO<sub>2</sub> and MnO<sub>2</sub> have  
49 similar capacities with only H<sup>+</sup> insertion, demonstrating a larger amount of competitive  
50 Zn<sup>2+</sup> insertion for TMA-MnO<sub>2</sub> in the Zn<sup>2+</sup>-containing electrolytes. To provide additional  
51 insights, we conducted experiments utilizing a non-protonic electrolyte of 2 M ZnSO<sub>4</sub> +  
52

65

0.2 M MnSO<sub>4</sub> in dimethyl sulfoxide (DMSO) (**Figure S7**). The discharge profiles of both materials exhibited a single, continuous Zn<sup>2+</sup> insertion behavior. Remarkably, TMA-MnO<sub>2</sub> demonstrated a higher discharge specific capacity of 246.2 mAh g<sup>-1</sup> compared to MnO<sub>2</sub> (190.1 mAh g<sup>-1</sup>) under the same conditions, indicating a greater Zn<sup>2+</sup> insertion capacity in TMA-MnO<sub>2</sub>. Furthermore, the enhanced Zn<sup>2+</sup> insertion is further verified by EDS elemental mapping. The TMA-MnO<sub>2</sub> maintains its 2D morphology even after discharge (**Figure S8**) and the distribution of Mn, O, and N elements remains uniform within the sample, indicating the structural integrity and stability. The discharge electrode exhibits a uniform distribution of Zn elements, indicating the insertion of Zn<sup>2+</sup>. Quantification from EDS analysis suggests a higher Zn/Mn atomic ratio for TMA-MnO<sub>2</sub> compared to MnO<sub>2</sub> (**Figure 4d and S9**).

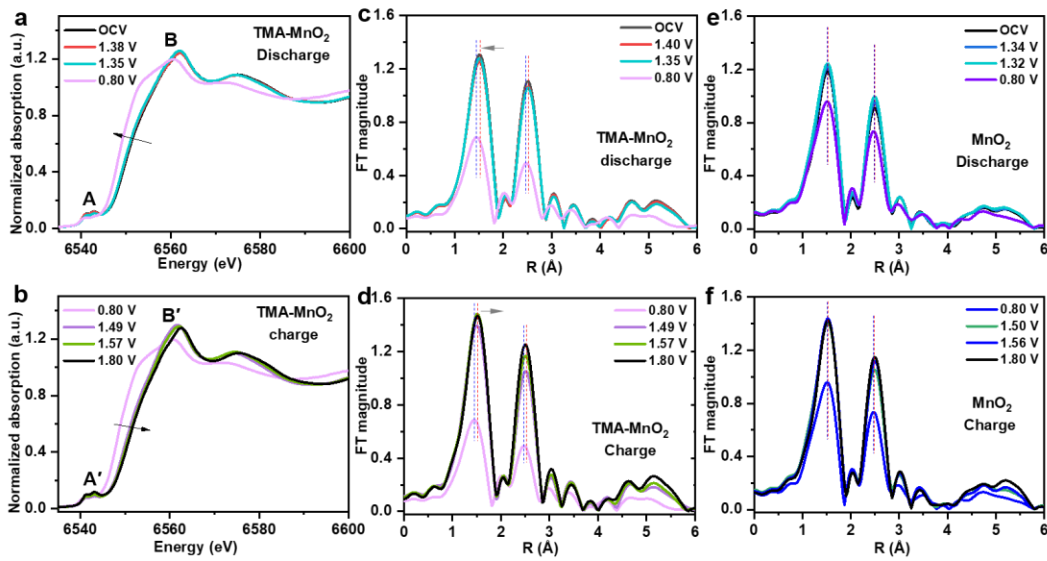

**Figure 4.** *In operando* pH change at **a)** MnO<sub>2</sub> and **b)** TMA-MnO<sub>2</sub> electrode interface-near region for the 1<sup>st</sup> discharge and charge cycle; **c)** Discharge curves of MnO<sub>2</sub> and TMA-MnO<sub>2</sub> electrode in 0.2 M MnSO<sub>4</sub> solution with and without 2 M ZnSO<sub>4</sub> as electrolytes at 0.05 A g<sup>-1</sup> in a three-electrode cell with an Ag/AgCl electrode as reference and Pt metal as counter electrode; **d)** The atomic ratios of Mn and Zn in the discharged MnO<sub>2</sub> and TMA-MnO<sub>2</sub> electrode. 2  
3  
4 Furthermore, *in operando* XAS was performed to reveal changes in the electronic  
5 structure and coordination environment of the Mn redox centers during the electrochemical  
6 processes (**Figure 5** and **S10**). The Mn oxidation states were explored by X-ray absorption  
7 near-edge structure (XANES) analysis. During the discharge process, the Mn K-edge and  
8 pre-edge peaks shift towards lower energy, indicating a decrease in the average valence  
9 state of Mn in TMA-MnO<sub>2</sub>. This is accompanied by a reduction in the intensity of the weak  
10 pre-edge peak, which is attributed to the decreased probability of transitions from the 1s  
11 into unoccupied 3d orbitals, partially allowed only due to electric quadrupole coupling  
12 and/or 3d-4p orbital mixing within the distorted MnO<sub>6</sub> octahedral framework. Note that the  
13 split in the pre-edge peaks arises from the separation of the degenerated 3d levels under an  
14 octahedral crystal field.<sup>43</sup> Two broad peaks of edge resonance (B) simultaneously move to  
15 lower energy with a decrease of intensity, which is attributed to energy absorption by core  
16 electrons.<sup>44</sup> During the following charge process, the Mn K-edge position shifts back to  
17 higher energy, demonstrating the reversible reduction and oxidation of Mn. The Mn K-  
18 edge XANES of the fresh and fully recharged electrodes are almost the same (**Figure S11**),  
19 indicating the very good reversibility of structural and electronic changes during cycling.

32

33 The changes in the local structure of Mn during the electrochemical processes were  
34 analyzed based on the phase uncorrected Fourier transform (FT) ( $k^3$ -weighted) of the V K-  
35 edge extended X-ray absorption fine structure (EXAFS). The initial TMA-MnO<sub>2</sub> electrode  
36 shows peaks in the radial distribution centered at  $\sim 1.5$  Å and  $2.5$  Å, corresponding to Mn-  
37 O and Mn-Mn distances, respectively.<sup>45</sup> During discharge, the FT amplitudes for both Mn-  
38 O and Mn-Mn distances decrease, attributed to the local structure distortion resulting from  
39 Jahn-Teller distortion associated with the reduction of the Mn oxidation state accompanied  
40 by the insertion of ions.<sup>46,47</sup> Compared to the EXAFS spectrum of MnO<sub>2</sub>, the amplitude  
41 decrease in TMA-MnO<sub>2</sub> was much larger, indicating larger local structure distortions in  
42 the TMA-MnO<sub>2</sub> electrode. The FT peaks for MnO<sub>2</sub> show no shift during discharge. In  
43 contrast, the FT peak shift is observed for TMA-MnO<sub>2</sub>, probably due to more competitive  
44 Zn<sup>2+</sup> intercalation.<sup>6,48</sup> At the fully discharged state, the two characteristic FT peaks are  
45 preserved, suggesting the stable Mn-O network in TMA-MnO<sub>2</sub> during ions insertion.  
46 During the following charging process, the amplitudes, and positions of the FT peaks for

## Conclusion

This study introduces the novel development of a MnO<sub>2</sub>/tetramethylammonium superstructure (TMA-MnO<sub>2</sub>) as a cathode material for aqueous zinc-ion batteries (AZIBs). The intercalation of TMA significantly expands the interlayer spacing of the MnO<sub>2</sub> matrix, facilitating the diffusion and preferential intercalation of Zn<sup>2+</sup> ions into the MnO<sub>2</sub> cathodes. This structural modification has led to a marked improvement in electrochemical performance, including a higher specific discharge capacity of 298 mAh g<sup>-1</sup> at 0.5 A g<sup>-1</sup>. Additionally, the cathode maintains a high capacity retention rate, delivering 263 mAh g<sup>-1</sup> after 200 cycles, corresponding to 88% capacity retention. Our innovative approach leverages *in operando* analysis to demonstrate how the TMA-MnO<sub>2</sub> superstructure effectively promotes Zn<sup>2+</sup> intercalation while simultaneously inhibiting competing H<sup>+</sup> intercalation. This dual function not only enhances the battery's performance but also mitigates the formation of the by-product zinc hydroxysulfate (ZHS), thereby enhancing the structural stability of the MnO<sub>2</sub>. Compared to existing literature, our TMA-MnO<sub>2</sub>

1  
2  
3  
4 cathodes show significant improvements over traditional MnO<sub>2</sub> electrodes, which typically  
5 exhibit lower Zn<sup>2+</sup> storage capacities and stability. For instance, Li et al. (ref 29) have  
6 reported maximum capacities around 195 mAh g<sup>-1</sup> at 0.3 A g<sup>-1</sup> and rapid capacity fading to  
7 113 mAh g<sup>-1</sup> within 100 cycles for similar systems. Similarly, Xie et al. (ref 31) found  
8 maximum capacities of around 150 mAh g<sup>-1</sup> at 2.0 A g<sup>-1</sup> with capacity fading to 80 mAh g<sup>-1</sup>  
9 within 200 cycles. Our approach not only surpasses these metrics but also addresses  
10 common challenges associated with ion co-intercalation. We envision further exploring the  
11 underlying mechanisms of ion intercalation and transport within layered structures like  
12 TMA-MnO<sub>2</sub>. We aim to synthesize and test other organic cation intercalated variants to  
13 broaden the applicability of this strategy to other types of rechargeable batteries.  
14 Additionally, scaling up this technology for commercial applications and optimizing the  
15 synthesis process to enhance the eco-friendliness and cost-effectiveness of the production  
16 are among our top priorities.
